

# Lecture 16: More on Classes (Chapter 17)

CS 1110  
Introduction to Computing Using Python

[E. Andersen, A. Bracy, D. Gries, L. Lee, S. Marschner, C. Van Loan, W. White]

## We know how to make:

- Class definitions
- Class specifications
- The `__init__` function
- Attributes (using `self`)
- Class attributes
- Class methods

4

## `__init__` is just one of many Special Methods

Start/end with 2 underscores

- This is standard in Python
- Used in all special methods
- Also for special attributes

`__init__` for initializer

`__str__` for `str()`

`__eq__` for `==`

`__lt__` for `<`, ...

```
class Point2():
    """Instances are points in 2D space"""
    def __init__(self,x=0,y=0):
        <snip>
    def __str__(self):
        """Returns: string with contents"""
        return '(' + str(self.x) + ', ' +
            str(self.y) + ')'
    def __eq__(self, other):
        """Returns: True if both coords equal"""
        return self.x == other.x
            and self.y == other.y
```

See Fractions example at the end of this lecture

Optional: for a complete list, see

<https://docs.python.org/3/reference/datamodel.html#basic-customization>

6

## Announcements

- [Prelim 2 alternate time request form](#) live due 4/1
  - Are you enrolled in? CHEM 2090, AEM 2601, ECON 1120, HADM 1360 → **FILL OUT THE SURVEY!**
- To reduce wait times during consulting hours:
  - If wait time exceeds 20 mins, we will shift to a 15-minutes-per-student system.
- Remember to reach out to your lab leads for lab-related support.
  - (<https://www.cs.cornell.edu/courses/cs1110/2022sp/timeplace/>)

Go over the "Rules to live by" slides

5

## Designing Types

- **Type**: set of values and the operations on them
  - **int**: (**set**: integers; **ops**: +, -, \*, /, ...)
  - **Point2** (**set**: x,y coordinates; **ops**: distanceTo, ...)
  - **Card** (**set**: suit \* rank combinations; **ops**: ==, !=, <)
  - Others to think about: *Person, Student, Image, Date, etc.*
- To define a class, think of a **type** you want to make

7

## Making a Class into a Type

- What values do you want in the set?
  - What are the attributes? What values can they have?
  - Are these attributes shared between instances (class attributes) or different for each instance (instance attributes)?
  - What are the *class invariants*: things you promise to keep true **after every method call** (see `n_credit invariant`)
- What operations do you want?
  - This often influences the previous question
  - What are the *method specifications*: states what the method does & what it expects (preconditions)
  - Are there any special methods that you will need to provide?

Write your code to make it so!

8

## Planning out a Class: Fraction

- What *attributes*? What *invariants*?
- What *methods*? What *initializer*? other *special methods*?

```
class Fraction:
    """Instance is a fraction n/d
    Attributes:
        numerator: top [int]
        denominator: bottom [int > 0] """

    def __init__(self, n=0, d=1):
        """Init: makes a Fraction"""
        assert type(n)==int
        assert type(d)==int and d>0
        self.numerator = n
        self.denominator = d
```

9

## What is equality?

```
f1 = Fraction(2,5)
f2 = Fraction(2,5)
if f1 == f2:
    # do we go here?
else:
    # or here?
```

By default, `==` compares *folder IDs*

10

## Operator Overloading: Equality

Implement `__eq__` to check for equivalence of two `Fractions` instead

```
class Fraction():
    """Instance attributes:
        numerator: top [int]
        denominator: bottom [int > 0]"""

    def __eq__(self,q):
        """Returns: True if self, q equal,
        False if not, or q not a Fraction"""
        if type(q) != Fraction:
            return False
        left = self.numerator*q.denominator
        right = self.denominator*q.numerator
        return left == right
```

11

## Problem: Doing Math is Unwieldy

### What We Want

$$\left(\frac{1}{2} + \frac{1}{3} + \frac{1}{4}\right) * \frac{5}{4}$$

Why not use the standard Python math operations?

### What We Get

```
>>> p = Fraction(1,2)
>>> q = Fraction(1,3)
>>> r = Fraction(1,4)
>>> s = Fraction(5,4)
>>> (p.add(q.add(r))).mult(s)
```

Seriously?

12

## Operator Overloading: Addition

```
class Fraction():
    """Instance attributes:
        numerator: top [int]
        denominator: bottom [int > 0]"""

    def __add__(self,q):
        """Returns: Sum of self, q
        Makes a new Fraction
        Precondition: q a Fraction"""
        assert type(q) == Fraction
        bot = self.denominator*q.denominator
        top = (self.numerator*q.denominator+
              self.denominator*q.numerator)
        return Fraction(top,bot)
```

```
>>> p = Fraction(1,2)
>>> q = Fraction(3,4)
>>> r = p+q
```

Python converts to

```
>>> r = p.__add__(q)
```

Operator overloading uses *method in object on left*.

13

## Operator Overloading: Multiplication

---

```
class Fraction():
    """Instance attributes:
        numerator: top [int]
        denominator: bottom [int > 0]"""
    >>> p = Fraction(1,2)
    >>> q = Fraction(3,4)
    >>> r = p*q

def __mul__(self,q):
    """Returns: Product of self, q
    Makes a new Fraction; does not
    modify contents of self or q
    Precondition: q a Fraction"""
    assert type(q) == Fraction
    top = self.numerator*q.numerator
    bot = self.denominator*q.denominator
    return Fraction(top,bot)
    >>> r = p.__mul__(q)
```

Python  
converts to
