

Lecture 20: while Loops (Sections 7.3, 7.4)

CS 1110

Introduction to Computing Using Python

[E. Andersen, A. Bracy, D. Gries, L. Lee, S. Marschner, C. Van Loan, W. White]

Recall: For Loops

- **loop sequence:** grades
- **loop variable:** x
- **body:** print(x)

To execute the for-loop:

1. Check if there is a “next” element of loop sequence
2. If so:
 - assign next sequence element to loop variable
 - Execute all of the body
 - Go back to Step 1
3. If not, terminate execution

Announcements

Different types of Repetition

1. Process each item in a sequence

- Compute statistics for a dataset
- Send all your contacts an email

```
for x in sequence:
    process x
```

2. Do something n times

- Draw a checkers board
- Run a protein-folding simulation for 10⁶ time steps

```
for x in range(n):
    do something
```

3. Do something an unknown number of times

- Play word guessing game until 6 strikes
- Go in current direction until edge is detected

???

Beyond Sequences: The while-loop

```
while <condition >:
    statement 1
    ...
    statement n
```

} body

Relationship to for-loop

- Broader notion of “keep working until done”
- Must explicitly ensure condition becomes false
- You explicitly manage what changes per iteration

While-Loops and Flow

```
import random

num = random.randint(0,10)
guessed_it = False
print("I'm thinking of a number.")

while not guessed_it:
    guess = int(input('Guess it: '))
    guessed_it = (num == guess)
    print('Well done!')
```

I'm thinking of a number.
Guess it: 6
Guess it: 2
Guess it: 1
Guess it: 4
Well done!

Continuation condition, not stopping condition

Q: What gets printed?

```

a = 8
b = 12
while a != b:
    if a > b:
        a = a - b
    else:
        b = b - a
print(a)

```

A: Infinite loop
 B: 8
 C: 12
 D: 4
 E: I don't know

This is Euclid's Algorithm for finding the greatest common factor of two positive integers.
Trivia: It is one of the *oldest* recorded algorithms (~300 B.C.)

8

for vs. while

- You can almost always use either
- Sometimes **for** is better
 - Do something a **fixed** (pre-determined) number of times
- Sometimes **while** is better
 - Do something an **indefinite** (not infinite) number of times
 - E.g., do something until some event happens, i.e., **until a stopping condition is reached**

Called "definite iteration"

Called "indefinite iteration"

10

for vs. while Task #1: do something n times

```

for k in range(n):
    # do something

```

```

k = 0
while k < n:
    # do something
    k = k+1

```

Must remember to increment

My preference? for-loop

11

for vs. while Task #2: do something an unknown number of times

??

```

for k in range(BIG_NUM):
    # do something
    if time to stop:
        break

```

```

while not time to stop:
    # do something

```

Do NOT use **break** in any work you submit in CS1110. Practice using **while**-loop in situations where **while**-loop is well suited

My preference? while-loop

12

for vs. while Task #3: do something to each element of a sequence

```

for k in range(len(seq)):
    seq[k] = seq[k]+1

```

```

k = 0
while k < len(seq):
    seq[k] = seq[k]+1
    k = k+1

```

while is more flexible, but sometimes requires more code

My preference? for-loop

13

for vs. while Task #4: do something until a limit is reached
 e.g., make a table of squares up to N

```

seq = [ ]
sqn= math.floor(sqrt(N))
for k in range(sqn+1):
    seq.append(k*k)

```

```

seq = [ ]
k = 0
while k*k < N:
    seq.append(k*k)
    k = k+1

```

for-loop requires you to know how many iterations you want **ahead of time**

can use complex expressions to check if a task is done

My preference? while-loop

14

for vs. while

Task #5: change a sequence's length

e.g., remove all 3's for List nums

```

for i in range(len(nums)):
    if nums[i] == 3:
        del nums[i]

```

```

while 3 in nums:
    nums.remove(3)

```

IndexError: list index out of range

is this not beautiful?

My preference? while-loop

15

for vs. while

Task #6: find 1st n Fibonacci numbers

Fibonacci numbers:

$$F_0 = 1 \quad F_1 = 1 \quad F_n = F_{n-1} + F_{n-2}$$

```

fib = [1, 1]
for k in range(2,n):
    fib.append(fib[-1] + fib[-2])

```

Last item in list

Second-last item in list

loop variable not always used

loop variable not always needed at all

```

fib = [1, 1]
while len(fib) < n:
    fib.append(fib[-1] + fib[-2])

```

My preference?

No strong preference

16

Using while-loops Instead of for-loops

Advantages

- Better for **modifying data**
 - More natural than range
 - Works better with deletion
- Better for **convergent tasks**
 - Loop until calculation done
 - Exact #steps are unknown
- Easier to **stop early**
 - Just set loop variable (e.g., keep_going) to False

Disadvantages

- **Infinite loops** happen more easily
 - Easy to forget loop vars
 - Or get continuation condition wrong
- **Require** more management
 - Initialize the condition?
 - Update the condition?

17

Setting up a while-loop

0. Situation is to do something until an event happens
1. Write the **continuation condition**
 - Create var names as necessary to express condition
 - May be easier to **negate stop** condition to get **continuation condition**
2. **Initialize loop vars** (vars in loop condition) as necessary
3. In loop body: **update loop vars** to possibly change loop condition from True to False
4. Write the rest of the loop body

18

Improve number guessing game

```

import random
min_num= 1
max_num= 10
max_chances= 5
secret_num= random.randint(min_num, max_num)
print("I have a number from "+str(min_num)+" to "+str(max_num))
print("You have "+str(max_chances)+" chances to guess it")

# User guesses until all chances used up or guessed correctly

```

1. Allow fixed number of guesses

For you to add later:

2. If a guess is wrong, tell player whether it was too high or too low.

19

Setting up a while-loop

0. Situation is to do something until an event happens
1. Write the **continuation condition**
 - Create var names as necessary to express condition
 - May be easier to **negate stop** condition to get **continuation condition**
2. **Initialize loop vars** (vars in loop condition) as necessary
3. In loop body: **update loop vars** to possibly change loop condition from True to False
4. Write the rest of the loop body
