Spring 2019 CS 1110 Final Exam

Please turn off and stow away all electronic devices. You may not use them for any reason during the exam. Do not bring them with you if you leave the room temporarily.

This is a closed book and notes examination. You may use the **2-sided reference sheet at the back of the exam.**

There are **7 problems**. Make sure you have the whole exam.

You have 150 minutes to complete 120 points. Use your time accordingly.

Question	Points	Score
1	9	
2	16	
3	20	
4	14	
5	22	
6	22	
7	17	
Total:	120	

It is a violation of the Academic Integrity Code to look at any exam other than your own, to look at any other reference material, or to otherwise give or receive unauthorized help.

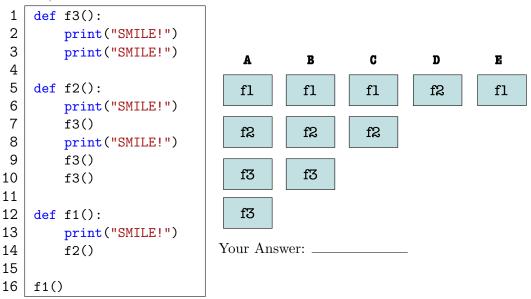

We also ask that you not discuss this exam with students who are scheduled to take a later makeup.

Academic Integrity is expected of all students of Cornell University at all times, whether in the presence or absence of members of the faculty. Understanding this, I declare I shall not give, use or receive unauthorized aid in this examination.

Signature:	Date
Name:	NetID

1. Try, Try Again

(a) [3 points] If Python has just finished printing "SMILE!" for the **5th time** and done nothing more, what does the call stack look like?

(b) [3 points] Suppose that fun1 is a class method for the class C and it has the following line of code in it:

$$a1 = b1 * 2$$

Where might the variable b1 that was referred to in this line of code be located?

- A. the global space
- B. the call frame for fun1

List all that apply: ____

- C. the call frame of the function that called fun1
- D. an instance/object attribute of an object of type C
- E. a class attribute of class C
- (c) [3 points] Consider a Person class with attributes children (a list of children) and n_male and n_female with the class invariant: n_male + n_female == len(children)

 Think about how one would implement the class method add_child(self, child, is_male).

 What is true of this invariant?

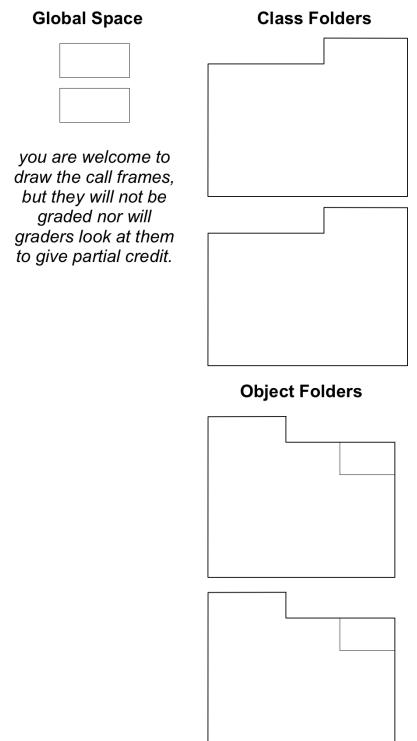

what is true of this invariant:

- A. If the invariant is ever not true, Python will throw an error.
- B. It must be true after every line of add_child executes.
- C. It must be true before and after add_child executes.
- D. A and B
- E. B and C
- F. A and C
- G. A, B, and C

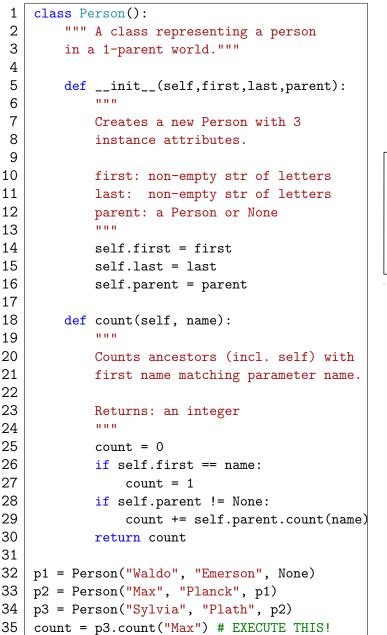

Your Answer: _____

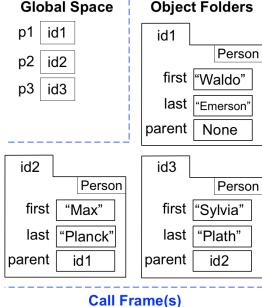

2. [16 points] **Keep it Classy**. Use the diagram on the right to show the state of Global Space, Class Folders, and Object folders after the code below finishes executing. You do **not** need to draw the call frames. This code runs without error.

3. [20 points] Another way to find Max. The drawing below shows the state of memory after executing lines 1-34 of the code, ignoring class folders for simplicity. Update the drawing, adding any call frame(s) or changes resulting from executing line 35. If you cross out a value or call frame, make sure it is still legible.

The next page is blank and can be used for scratch work.

You may use this blank page for scratch work. Graders will not look at this page unless you clearly instruct them to do so on another page.

4. [14 points] More than a Person. The definition of the Person class from the previous question is copied here for your convenience. Define a subclass of Person called Student. A Student has the attributes of a Person plus one additional attribute, netID.

```
class Person():
    """ A class representing a person
    in a 1-parent world."""

def __init__(self,first,last,parent):
    """
    Creates a new Person with 3
    instance attributes.

first: non-empty str of letters
    last: non-empty str of letters
    parent: a Person or None
    """
    self.first = first
    self.last = last
    self.parent = parent
```

netID is not a parameter to any __init__ method; it is a string that is created at initialization by concatenating 3 things:

- 1. the *lower-case* first letter of the **first** name
- 2. the lower-case first letter of the last name
- 3. a unique number across all students representing when the Student was created. (Note: this is a simplification of how Cornell actually assigns your netID a number.)

Examples:

The very first student at Cornell, Ezra Cornell, has netID "ec1".

The second student at Cornell, Pearl Buck, has netID "pb2".

The third student at Cornell, Martha Pollack, has netID "mp3".

Your subclass should make use of the Person class functionality and avoid code redundancy. Do **not** worry about enforcing preconditions, writing comments, or docstrings.

- 5. **The Sorted Hat.** In this question you will consider two approaches to implementing the function <code>is_sorted</code>, which determines whether a list of integers <code>b</code> is sorted (in ascending order) or not. In *neither* part are you responsible for asserting/enforcing preconditions.
 - (a) [12 points] While Loops and Loop Invariants. This version is implemented using a while loop. You are given the precondition, postcondition, the loop invariant, and the structure of the while loop. You must provide the initialization, the loop condition, and the loop body.

```
def is_sorted(b):
    0.00
    Returns: True if b is sorted in ascending order, False otherwise
    b: a list of integers with at least 1 element; remains unchanged
    Examples:
    is_sorted([3]) Returns True
    is_sorted([3,3]) Returns True
    is_sorted([3,4]) Returns True
    is_sorted([-4,1,-12]) Returns False
    # PRE: b is a list of integers with at least 1 element
    # TASK #1: initialize these 2 variables so that the loop
    # invariant is true at the start
   sorted_this_far = _____
    # INV: sorted_this_far is True if b[0..k] is sorted, otherwise False
    # TASK #2: provide the loop condition so that the loop
    # terminates as soon as it knows the list is not sorted
    # Also, make sure you do not inspect past the end of the list
    while (__
        # TASK #3: provide the loop body
       k = k + 1
    # POST: sorted_this_far is True if b is sorted, otherwise False
    # TASK #4: what should this function return?
    return _
```

(b) [10 points] **Recursion.** Make effective use of **recursion** to provide a second implementation of <code>is_sorted</code>. Your solution must use recursion in order to receive points. When you have finished, step through your code to make sure it works on the given examples. The spec has been copied for your convenience.

```
def is_sorted(b):
    """

Returns: True if b is sorted in ascending order, False otherwise

b: a list of integers with at least 1 element; remains unchanged

Examples:
    is_sorted([3]) Returns True
    is_sorted([3,3]) Returns True
    is_sorted([3,4]) Returns True
    is_sorted([-4,1,-12]) Returns False
```

6. **Shop till you drop!** For this question, you will answer questions about and also help complete a new class called **Product**.

- (a) [10 points] Complete the __init__ method above according to its specification. Be sure to assert all of the stated preconditions.
- (b) [2 points] Why is the attribute SALES_TAX_RATE in all caps?

 Answer in 1 sentence and be succinct. Irrelevant statements will cost you points.

(c) [4 points] This page continues the Product class definition from the previous page. Complete the __str__ method below according to its specification.

```
def __str__(self):
```

Returns: a [str] representation of the Product, including all 4 attributes separated by commas, in a string form. The price should have a dollar sign. Don't worry about extending the price to exactly 2 decimal places.

Example: "Milk, \$3.0, 10, True"

(d) [4 points] Complete the __eq__ method below according to its specification.

```
def __eq__(self, other):
    """Returns: True if other is a Product and both self and other
    have the same name, price, and tax-exempt status. False otherwise.
    """
```

(e) [2 points] You aren't sure whether your __eq__ method is being called or not. Maybe you gave it the wrong name? Maybe the underscores are wrong? You're not sure. Explain how you could modify __eq__ above so that you could find out whether __eq__ ever gets called. Your solution should work without modifying any other aspects of the Product class.

- 7. What's in store for you? Do not start this question until you have given the previous question a serious attempt. This question introduces a Store class; Stores contain Products.
 - (a) [12 points] **List version.** Complete the **stock** method below according to its specification. You do **not** need to assert any preconditions.

```
class Store():
    """An instance represents a named store with goods to sell
   INSTANCE ATTRIBUTES:
   name: the name of the store [str], Example: "Aldi"
   goods: a list of Product that the store has in stock """
   def __init__(self, name):
       """Creates a new store called "name" with 2 attributes:
       name: a non-empty str, e.g. 'Aldi'
       goods:
                   a (possibly empty) list of Product """
          Implementation left out; you do not need to complete it
   def stock(self, p):
        """ p: a Product to be added to the store
       - If p is NOT already in the store, add p to the
            store's goods.
       - If p IS already there, increase the store's products's
        inventory (quantity) by the quantity in the parameter p.
       Using "in" to test if p is already on the list WILL NOT WORK.
       Instead, check each element in goods for equality with p,
       making use of the equals method you wrote for Product. """
```

(b) [5 points] **Dictionary version.** Did you notice on the previous page how tedious it was to check every element in the store to see whether a particular product was present? This page presents an **alternate** definition of **Store** in which **goods** is a *dictionary*, not a list. Re-implement the **stock** method below. The specification has changed slightly because **goods** is now a *dictionary*, not a list. You do **not** need to assert any preconditions. You may find the Dictionary Operations on the Reference Sheet helpful.

```
class Store():
    """An instance represents a named store with goods to sell
    INSTANCE ATTRIBUTES:
    name: the name of the store [str], Example: "Aldi"
    goods: a dictionary keeping track of inventory.
           Each key is a str (the name of the Product). Note: we can
              no longer keep inventory for two Products that have the
              same name but different prices or tax-exemption status.
           Each value is a Product.
    Example:
          s = Store("Aldi")
          p1 = Product("Milk", 3.0, 10, True);
          s.goods[p1.name] = p1 # overwrites any existing Product w/ same name
          s.goods["Milk"] = p1 # alternative to the previous line """
   init implementation omitted for space. You do not need to complete it.
    def stock(self, p):
        """ p: a Product to be added to the store
        - If a Product with the same name as p is NOT already in the
            store, add p to the store's goods.
        - If a Product with the same name as p IS already there, ignore
            any price/exemption difference; increase the store's products's
            inventory (quantity) by the quantity in the parameter p.
        Using "in" to test if p is already in the dictionary WORKS! """
```

Spring 2019 CS 1110 Reference Sheet

We recommend that you draw vertical lines to make your indentation clear:

```
def my_function():
    if something:
        do something
        do another thing
    do this thing last
```

Dictionary Operations		
len(d)	Returns: number of keys in dictionary d; it can be 0.	
y in d	Returns: True if y is a key d; False otherwise.	
d[k] = v	Assigns value v to the key k in d.	
d[k]	If value v was assigned to the key k in d, d[k] evaluates to v.	
del d[k]	Deletes the key k (and its value) from the dictionary d.	
d.clear()	Removes all keys (and values) from the dictionary d.	
d.keys()	Returns: an iterator of all the keys in dictionary d.	
d.values()	Returns: an iterator of all the values in dictionary d.	

List methods		
lt[i:j]	Returns: a new list[lt[i], lt[i+1],, lt[j-1]] under ordinary circum-	
	stances. Returns [] if i and j are not both sensible indices.	
lt.append(item)	Adds item to the end of list lt	
lt.count(item)	Returns: count of how many times item occurs in list 1t	
lt.index(item)	Returns: index of first occurrence of item in list 1t 1t; raises an error if item	
	is not found. (There's no "find" for lists.)	
<pre>lt.index(y,n)</pre>	Returns: index of first occurrence of y in list 1t STARTING at position n;	
	raises an error if y does not occur in lt.	
lt.insert(i,item)	Insert item into list 1t at position i	
lt.pop(i)	Returns: element of list 1t at index i and also removes that element from	
	the list lt. Raises an error if i is an invalid index.	
lt.remove(item)	Removes the first occurrence of item from list lt; raises an error if item not	
	found.	
lt.reverse()	Reverses the list 1t in place (so, 1t is modified)	
lt.sort()	Rearranges the elements of x to be in ascending order.	

	String methods
s.count(s1)	Returns: the number of times s1 occurs in string s
s.find(s1)	Returns: index of first occurrence of string s1 in string s (-1 if not found)
s.find(s1,n)	Returns: index of first occurrence of string s1 in string s STARTING at position
	n. (-1 if s1 not found in s from this position)
s.isalpha()	Returns: True if s is not empty and its elements are all letters; it returns False
	otherwise.
s.isdigit()	Returns: True if s is not empty and its elements are all numbers; it returns False
	otherwise.
s.islower()	Returns: True if s is has at least one letter and all letters are lower case; returns
	False otherwise $(e.g., `a123' \text{ is True but '}123' \text{ is False}).$
s.isupper()	Returns: True if s is has at least one letter and all letters are upper case; returns
	False otherwise $(e.g., 'A123')$ is True but '123' is False).
s.lower()	Returns: a copy of s, all letters converted to lower case.
s.join(slist)	Returns: a string that is the concatenation of the strings in list slist separated
	by string s
s.replace(a,b)	Returns: a copy of s where all instances of a are replaced with b
s.split(sep)	Returns: a list of the "words" in string s, using sep as the word delimiter (whites-
	pace if sep not given)
s.strip()	Returns: copy of string s where all whitespace has been removed from the begin-
	ning and the end of s. Whitespace not at the ends is preserved.
s.upper()	Returns: a copy of s, all letters converted to upper case.
s[i:j]	Returns: if i and j are non-negative indices and $i \leq j-1$, a new string containing
	the characters in s from index i to index j-1, or the substring of s starting at i
	if $j \ge len(s)$

Other useful functions		
a in s	Returns: True if the substring a is in s; False otherwise.	
isinstance(o, c)	Returns: True if o is an instance of class c; False otherwise.	
len(s)	Returns: number of characters in s; it can be 0.	
list(range(n))	Returns: the list [0 n-1]	
<pre>list(filter(func, lt))</pre>	Returns: a list of elements of 1t for which function func returns True	
list(map(func, lt))	Returns: A list obtained by applying function func to each element in	
	list 1t and concatenating the results of each application.	
range(a)	Returns: an iterable for processing elements (0,1,,a-1).	
range(a,b)	Returns: an iterable for processing elements (a,a+1,,b-1).	
range(a,b,n)	Returns: an iterable for elements $(a,a+n,,a+n*(b-a-1)//n)$.
