

Key-Value Pairs

- The last built-in type: **dictionary** (or **dict**)
 - One of the most important in all of Python
 - Like a list, but built of key-value pairs
- Keys:** Unique identifiers
 - Think social security number
 - At Cornell we have netids: jrs1
- Values:** Non-unique Python values
 - John Smith (class '13) is jrs1
 - John Smith (class '16) is jrs2

Idea: Lookup values by keys

1

Basic Syntax

- Create with format: {k1:v1, k2:v2, ...}
 - Both keys and values must exist
 - Ex:** d={'jrs1':'John','jrs2':'John','wmw2':'Walker'}
- Keys** must be **non-mutable**
 - ints, floats, bools, strings, tuples
 - Not** lists or custom objects
 - Changing a key's contents hurts lookup
- Values** can be **anything**

2

Using Dictionaries (Type dict)

- Access elts. like a list
 - d['jrs1'] evals to 'John'
 - d['jrs2'] does too
 - d['wmw2'] evals to 'Walker'
 - d['abel'] is an **error**
- Can test if a key exists
 - 'jrs1' in d evals to **True**
 - 'abel' in d evals to **False**
- But cannot slice ranges!

d = {'jrs1':'John','jrs2':'John',
'wmw2':'Walker'}

Key-Value order in folder is not important

3

Dictionaries Can be Modified

- Can reassign values
 - d['jrs1'] = 'Jane'
 - Very similar to lists
- Can add new keys
 - d['aaa1'] = 'Allen'
 - Do not think of order
- Can delete keys
 - del d['wmw2']
 - Deletes both key, value

d = {'jrs1':'John','jrs2':'John',
'wmw2':'Walker'}

4

Dictionaries: Iterable, but not Sliceable

- Can loop over a dict
 - Only gives you the keys
 - Use key to access value
- Can iterate over values
 - Method:** d.values()
 - But no way to get key
 - Values are not unique

```
for k in d:
    # Loops over keys
    print(k)    # key
    print(d[k]) # value
```

```
# To loop over values only
for v in d.values():
    print(v)    # value
```

5

Dictionary Loop with Accumulator

```
def max_grade(grades):
    """Returns max grade in the grade dictionary
    Precondition: grades has netids as keys, ints as values"""
    maximum = 0          # Accumulator
    # Loop over keys
    for k in grades:
        if grades[k] > maximum:
            maximum = grades[k]
    return maximum
```

6

Dictionaries and Mutable Functions

- Restrictions are different than list
 - Okay to loop over dictionary to change
 - You are looping over *keys*, not *values*
 - Like looping over positions
- But you **may not add or remove** keys!
 - Any attempt to do this will fail
 - Have to create a key list if you want this

7

But This is Okay

```
def add_bonus(grades,bonus):
    """Gives bonus points to everyone in grades

    Precondition: grades has netids as keys, ints as values.
    bonus is an int."""
    # No accumulator. This is a procedure

    for student in grades:
        # Modifies the dictionary, but does not change keys
        grades[student] = grades[student]+bonus
```

8

Nesting Dictionaries

- Remember, values can be anything
 - Only restrictions are on the keys
- Values can be lists (**Visualizer**)
 - `d = {'a':[1,2], 'b':[3,4]}`
- Values can be other dicts (**Visualizer**)
 - `d = {'a':{'c':1,'d':2}, 'b':{'e':3,'f':4}}`
- Access rules similar to nested lists
 - Example:** `d['a']['d'] = 10`

9

Example: JSON File

```
{
  "wind": {
    "speed": 13.0,
    "crosswind": 5.0
  },
  "sky": [
    {
      "cover": "clouds",
      "type": "broken",
      "height": 1200.0
    },
    {
      "type": "overcast",
      "height": 1800.0
    }
  ],
  {
    "type": "overcast",
    "height": 1800.0
  }
}
```

- JSON:** File w/ Python dict
 - Actually, minor differences
- weather.json:**
 - Weather measurements at Ithaca Airport (2017)
 - Keys:** Times (Each hour)
 - Values:** Weather readings
- This is a *nested* JSON
 - Values are also dictionaries
 - Containing more dictionaries
 - And also containing lists

10

Dictionaries and Recursion

- Dictionaries are **not sliceable**
 - Makes it difficult to do divide and conquer
 - So rare to be used in recursion by itself
 - Often the *answer* to a recursion, not the *input*
- However, the **key list** is sliceable
 - Can recurse on key list, not the dict
 - This requires a helper function
 - Helper is recursive, not the main function

11

The Recursive Version

```
def max_grade_helper(netids,grades):
    """Returns max grade among given netids

    Precond: netids a list of keys in grades, grades a dict w/ int values"""
    # Process small data
    if len(netids) <= 1:
        return grades[netids[0]] if len(netids) == 1 else 0

    # Break it up into left and right
    left = grades[netids[0]]
    right = max_grade_helper(netids[1:],grades)

    # Combine the answers
    return max(left,right)
```
