Lecture 19

Using Classes Effectively

Announcements for Today

Assignments

- A4 should be done
 - But the survey is still open
- A5 to be posted tonight
 - Short written assignment
 - Due next Thursday
- A6 also posted tonight
 - Due November 14th
 - Follow the microdeadlines!
 - Get started on it first

Optional Videos

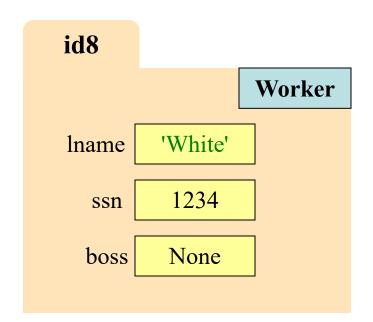

- Videos 20.9-20.10 today
- Also Lesson 21 for today
- Lesson 22 for next time

Recall: The __init__ Method

```
two underscores
 w - worker (Opama', 1234, None)
 <u>__init__(self</u>, n, s, b):
"""Initializer: creates a Worker
Has last name n, SSN s, and boss b
Precondition: n a string,
s an int in range 0..999999999,
b either a Worker or None.
self.lname = n
self.ssn = s
self.boss = b
```

Called by the constructor

Recall: The __init__ Method

```
two underscores
w - worker (Opama', 1234, None)
```

```
def __init__(self, n, s, b):
```

"""Initializer: creates a Worker

Has last name n, SSN s, and boss b

Precondition: n a string, s an int in range 0..99999999, b either a Worker or None. """

```
self.lname = n
self.ssn = s
```

self.boss = b

Are there other special methods that we can use?

Example: Converting Values to Strings

str() Function

- Usage: str(<expression>)
 - Evaluates the expression
 - Converts it into a string
- How does it convert?
 - $str(2) \rightarrow '2'$
 - $str(True) \rightarrow 'True'$
 - $str('True') \rightarrow 'True'$
 - $str(Point3()) \rightarrow '(0.0,0.0,0.0)'$

repr() Function

- Usage: repr(<expression>)
 - Evaluates the expression
 - Converts it into a string
- How does it convert?
 - repr(2) \rightarrow '2'
 - repr(True) → 'True'
 - repr('True') → "'True'"
 - repr(Point3()) \rightarrow "<class 'Point3'> (0.0,0.0,0.0)"

Example: Converting Values to Strings

str() Function

- Usage: str(<expression>)
 - Evaluates the expression
 - Converts it into a string
- How does it con
 - $str(2) \rightarrow '2'$
 - str(True) → 'True
 - str('True') → 'True'
 - $str(Point3()) \rightarrow '(0.0,0.0,0.0)'$

repr() Function

repr() is for unambigious representation

How does it co

- repr(2) \rightarrow '2'
- The value's type is clear
- repr(True) \rightarrow
- repr('True') \rightarrow "'True'"
- repr(Point3()) \rightarrow "<class 'Point3'> (0.0,0.0,0.0)"

What type is

this value?

What Does str() Do On Objects?

Does NOT display contents

```
>>> p = Point3(1,2,3)
>>> str(p)
'<Point3 object at 0x1007a90>'
```

- Must add a special method
 - str_ for str()
 - repr_ for repr()
- Could get away with just one
 - repr() requires __repr__
 - str() can use __repr__(if __str__ is not there)

```
class Point3(object):
```

```
"""Class for points in 3d space"""
def str (self):
  """Returns: string with contents"""
  return '('+str(self.x) + ',' +
             str(self.y) + ',' +
             str(self.z) + ')'
def __repr__(self):
  """Returns: unambiguous string"""
  return str(self. class )+
          str(self)
```

What Does str() Do On Objects?

Does NOT display contents

```
>>> p = Point3(1,2,3)
>>> str(p)
'<Point3 object at 0x1007a90>'
```

- Must add a special method
 - str_ for str()
 - repr_ for repr()
- Could get away with just one
 - repr() requires __repr__
 - str() can use __repr__(if __str__ is not there)

```
class Point3(object):
   """Class for points in 3d space"""
   def str (self):
      """Returns: string with contents"""
      return '('+str(self.x) + ',' +
                 str(self.y) + ',' +
                 str(self.z) + ')'
                            Gives the
   def __repr__(self):
                            class name
      """Returns: unambigy <u>s string</u>
      return str(self.__class___)+
             str(self)
                             _repr__ using
```

as helper

```
class Example(object):
  """A simple class"""
  def ___init___(self,x):
     self.x = x
  def __str__(self):
     return 'Value '+str(self.x)
  def __repr__(self):
     return 'Example['+str(x)+']'
```

```
>>> a = Example(3)
>>> str(a) # a.__str()__
```

What is the result?

A: '3'

B: 'Value 3'

C: 'Example[3]'

D: Error

E: I don't know

```
class Example(object):
                                  >>> a = Example(3)
  """A simple class"""
                                  >>> str(a)
                                   What is the result?
  def ___init___(self,x):
    self.x = x
                                   B: 'Value 3'
  def __str__(self):
    return 'Value '+str(self.x)
                                   C: 'Example[3]'
                                   D: Error
  def __repr__(self):
    return 'Example['+str(x)+']'
                                  E: I don't know
```

```
class Example(object):
  """A simple class"""
  def ___init___(self,x):
     self.x = x
  def __str__(self):
     return 'Value '+str(self.x)
  def __repr__(self):
     return 'Example['+str(x)+']'
```

```
>>> a = Example(3)
```

>>> repr(a)

What is the result?

A: '3'

B: 'Value 3'

C: 'Example[3]'

D: Error

E: I don't know

```
class Example(object):
                                  >>> a = Example(3)
  """A simple class"""
                                  >>> repr(a)
  def ___init___(self,x):
                                   What is the result?
    self.x = x
                                   B: 'Value 3'
  def __str__(self):
    return 'Value '+str(self.x)
                                   C: 'Example[3]'
                                   D: Error
  def __repr__(self):
    return 'Example['+str(x)+']'
                                  E: I don't know
                     No self
```

Designing Types

From first day of class!

- Type: set of values and the operations on them
 - int: (set: integers; ops: +, -, *, //, ...)
 - Time (set: times of day; ops: time span, before/after, ...)
 - Worker (set: all possible workers; ops: hire,pay,promote,...)
 - Rectangle (set: all axis-aligned rectangles in 2D;ops: contains, intersect, ...)
- To define a class, think of a *real type* you want to make
 - Python gives you the tools, but does not do it for you
 - Physically, any object can take on any value
 - Discipline is required to get what you want

Making a Class into a Type

- 1. Think about what values you want in the set
 - What are the attributes? What values can they have?
- 2. Think about what operations you want
 - This often influences the previous question
- To make (1) precise: write a *class invariant*
 - Statement we promise to keep true after every method call
- To make (2) precise: write *method specifications*
 - Statement of what method does/what it expects (preconditions)
- Write your code to make these statements true!

```
class Time(object):
  """Class to represent times of day.
  Inv: hour is an int in 0..23
  Inv: min is an int in 0..59"""
  def ___init___(self, hour, min):
     """The time hour:min.
     Pre: hour in 0..23; min in 0..59"""
  def increment(self, hours, mins):
     """Move time hours and mins
     into the future.
     Pre: hours int \geq= 0; mins in 0..59"""
  def isPM(self):
```

"""Returns: True if noon or later."""

Class Invariant

States what attributes are present and what values they can have.

A statement that will always be true of any Time instance.

Method Specification

States what the method does.

class Rectangle(object):

"""Class to represent rectangular region

Inv: t (top edge) is a float Inv: l (left edge) is a float

Inv: b (bottom edge) is a float Inv: r (right edge) is a float

Additional Inv: l <= r and b <= t."""

def __init__(self, t, l, b, r):

"""The rectangle [l, r] x [t, b]

Pre: args are floats; l <= r; b <= t"""

def area(self):

"""Return: area of the rectangle."""

def intersection(self, other):

"""Return: new Rectangle describing intersection of self with other."""

Class Invariant

States what attributes are present and what values they can have.

A statement that will always be true of any Rectangle instance.

Method Specification

States what the method does.

class Rectangle(object):

"""Class to represent rectangular region

Inv: t (top edge) is a float Inv: l (left edge) is a float

Inv: b (bottom edge) is a float

Inv: r (right edge) is a float

Additional Inv: $l \le r$ and $b \le t$."""

Class Invariant

States what attributes are present and what values they can have.

A statement that will always be true of any Rectangle instance.

def __init__(self, t, l, b, r):
 """The rectangle [l, r] x [t, b
 Pre: args are floats; l <= r; l</pre>

Special invariant **relating** attributes to each other

def area(self):

"""Return: area of the rectangle."""

def intersection(self, other):

"""Return: new Rectangle describing intersection of self with other."""

Method Specification

States what the method does.

class Hand(object):

"""Instances represent a hand in cards.

Inv: cards is a list of Card objects.

This list is sorted according to the ordering defined by the Card class."""

def __init__(self, deck, n):

"""Draw a hand of n cards.

Pre: deck is a list of >= n cards"""

def isFullHouse(self):

"""Return: True if this hand is a full house; False otherwise"""

def discard(self, k):

"""Discard the k-th card."""

Class Invariant

States what attributes are present and what values they can have.

A statement that will always be true of any Rectangle instance.

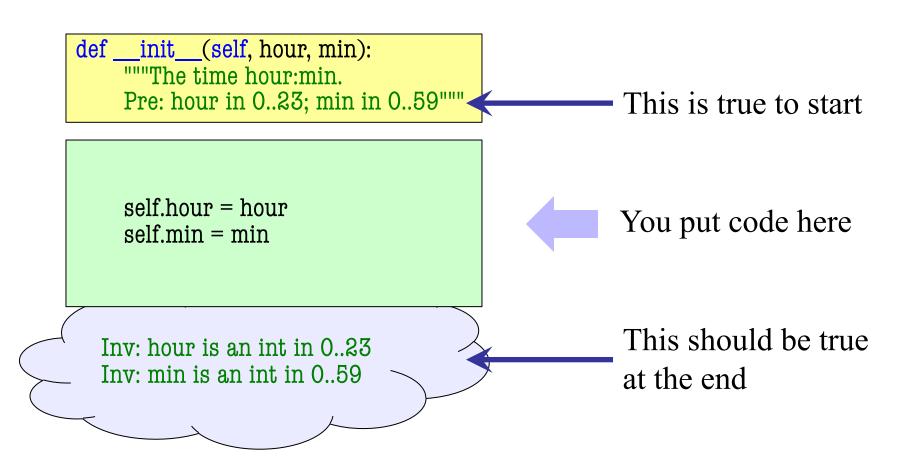

Method Specification

States what the method does.

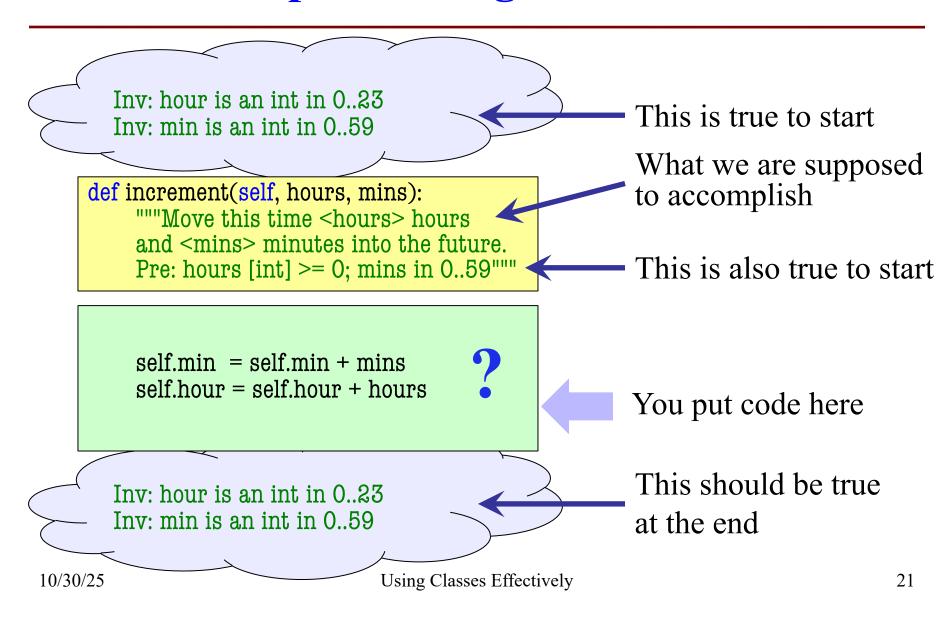

Implementing a Class

- All that remains is to fill in the methods. (All?!)
- When implementing methods:
 - 1. Assume preconditions are true
 - 2. Assume class invariant is true to start
 - 3. Ensure method specification is fulfilled
 - 4. Ensure class invariant is true when done
- Later, when using the class:
 - When calling methods, ensure preconditions are true
 - If attributes are altered, ensure class invariant is true

Implementing an Initializer

Implementing a Method

Implementing a Method

Inv: hour is an int in 0..23 Inv: min is an int in 0..59 What we are supposed def increment(self, hours, mins): to accomplish """Move this time <hours> hours and <mins> minutes into the future. Pre: hours [int] \geq = 0; mins in 0..59""" This is also true to start self.min = self.min + mins self.hour = (self.hour + hours + self.min // 60)self.min = self.min % 60 You put code here self.hour = self.hour % 24 This should be true Inv: hour is an int in 0..23 Inv: min is an int in 0..59 at the end 10/30/25 Using Classes Effectively

Object Oriented Design

Interface

- How the code fits together
 - interface btw programmers
 - interface btw parts of an app
- Given by specifications
 - Class spec and invariants
 - Method specs and preconds
 - Interface is ALL of these

Implementation

- What the code actually does
 - when create an object
 - when call a method
- Given by method definitions
 - Must meet specifications
 - Must not violate invariants
 - But otherwise flexible

Important concept for making large software systems

Implementing a Class

- All that remains is to fill in the methods. (All?!)
- When implementing methods:
 - 1. Assume preconditions are true
 - 2. Assume class invariant is true to start
 - 3. Ensure method specification is fulfilled
 - 4. Ensure class invariant is true when done
- Later, when using the class:
 - When calling methods, ensure preconditions are true
 - If attributes are altered, ensure class invariant is true

Recall: Enforce Preconditions with assert

def anglicize(n):

```
"""Returns: the anglicization of int n.

Precondition: n an int, 0 < n < 1,000,000"""

assert type(n) == int, str(n)+' is not an int'

assert 0 < n and n < 1000000 repr(n)+' is out of range'

# Implement method here...
```

Check (part of) the precondition

(Optional) Error message when precondition violated

Enforce Method Preconditions with assert

class Time(object):

"""Class to represent times of day."""

Inv: hour is an int in 0..23 Inv: min is an int in 0..59"""

def __init__(self, hour, min):

"""The time hour:min. Pre: hour in 0..23; min in 0..59""" assert type(hour) == int assert 0 <= hour and hour < 24 assert type(min) == int

Initializer creates/initializes all of the instance attributes.

Asserts in initializer guarantee the initial values satisfy the invariant.

def increment(self, hours, mins):

assert $0 \le \min$ and $\min < 60$

"""Move this time <hours> hours and <mins> minutes into the future. Pre: hours is int \geq = 0; mins in 0..59""" assert type(hour) == int assert type (min) == int assert hour ≥ 0 $^{10/3}_{\text{assert 0}} < = \min \text{ and } \min < 60$ Using Classes Effectively

Asserts in other methods enforce the method preconditions.

Hiding Methods From Access

- Hidden methods
 - start with an underscore
 - do not show up in help()
 - are meant to be internal (e.g. helper methods)
- But they are not restricted
 - You can still access them
 - But this is bad practice!
 - Like a precond violation
- Can do same for attributes
 - Underscore makes it hidden
 - Only used inside of methods

```
class Time(object):
```

"""Class to represent times of day.

Inv: hour is an int in 0..23 Inv: min is an int in 0..59"""

def _is_minute(self,m):

"""Return: True if m valid minute"""
return (type(m) == int and
m >= 0 and m < 60)

def __init__(self, hour, min):

"""The time hour:min.

Pre: hour in 0..23; min in 0..59"""

assert self._is_minute(m)

Helper

Hiding Methods From Access

- Hidden methods
 - start with an underscore
 - do not show up in help()
 - are meant to be internal (e.g. helper methods)
- But they are not restricted
 - You can still access them
 - But this is bad practice!
 - Like a precond violation
- Can do same for attributes

Will come back to this

```
class Time(object):
       """Class to represent times of day.
       Inv: hour is an int in 0..23
            min is an int in 0..59"""
HIDDEN
       def is minute(self,m):
          """Return: True if m valid minute"""
          return (type(m) == int and
                  m >= 0 \text{ and } m < 60)
       def ___init___(self, hour, min):
          """The time hour:min.
          Pre: hour in 0..23; min in 0..59"""
          assert self._is_minute(m)
                             Helper
```

Enforcing Invariants

class Time(object):

"""Class to repr times of day.

Inv: hour is an int in 0..23 Inv: min is an int in 0..59

Invariants:

Properties that are always true.

These are just comments!

How do we prevent this?

- Idea: Restrict direct access
 - Only access via methods
 - Use asserts to enforce them
- Example:

```
def getHour(self):
    """Returns: the hour"""
    return self.hour

def setHour (self,value):
    """Sets hour to value"""
    assert type(value) == int
    assert value >= 0 and value < 24
    self.numerator = value</pre>
```

Data Encapsulation

- Idea: Force the user to only use methods
- Do not allow direct access of attributes

Setter Method

- Used to change an attribute
- Replaces all assignment statements to the attribute
- **Bad**:

Good:

>>> t.setHour(5)

Getter Method

- Used to access an attribute
- Replaces all usage of attribute in an expression
- **Bad**:

>>>
$$x = 3*t.hour$$

Good:

$$>> x = 3*t.getHour()$$

Data Encapsulation

class Time(object):

"""Class to repr times of day. """

NO ATTRIBUTES

in class specification

Getter

def getHour (self):

"""Returns: hour attribute"""
return self._hour

Method specifications

describe the attributes

Setter

def setHour(self, h):

""" Sets hour to h
Pre: h is an int in 0..23"""
assert type(h) == int
assert 0 <= h and h < 24
self._hour = d

Setter precondition is same as the **invariant**

Data Encapsulation

class Time(object): **NO ATTRIBUTES** """Class to repr times of day. """ in class specification Getter def getHour (self): **Method specifications** """Returns: hour attribute""" describe the attributes return self._hour Setter def setHour(Hidden attribute user """ Sets ho **econdition** is should **NOT** know about Pre: h is a same as the invariant assert type(h) == int assert $0 \le h$ and $h \le 24$ self._hour = d

Encapsulation and Specifications

class Time(object):

"""Class to represent times of day. """

No attributes in class spec

```
### Hidden attributes
# Att _hour: hour of the day
# Inv: _hour is an int in 0..23
# Att _min: minute of the hour
# Inv: _min is an int in 0..59
```

These comments
make it part of the
class invariant
but not part of the
(public) interface

These comments do not go in help()

Class Invariant vs Interface

Class Invariant

- List attributes that are present
 - Both hidden AND unhidden
 - Lists the invariants of each
- For the implementer
 - Guide for the initializer
 - Guide for method definitions

Interface

- Describes what is accessible
 - Unhidden methods/attribs
 - What is visible in help()
- For user/other programmers
 - Enough to create an object
 - Enough to call the methods

Early years of CS1110 confused these two topics

Mutable vs. Immutable Attributes

Mutable

- Can change value directly
 - If class invariant met
 - **Example:** turtle.color
- Has both getters and setters
 - Setters allow you to change
 - Enforce invariants w/ asserts

Immutable

- Can't change value directly
 - May change "behind scenes"
 - **Example:** turtle.x
- Has only a getter
 - No setter means no change
 - Getter allows limited access

May ask you to differentiate on the exam

Mutable vs. Immutable Attributes

Mutable

Can change value directly

- If class invariant met
- **Example:** turtle.color
- Has both getters and setters
 - Setters allow

Where?

Enforce invar Next Thursday

Can't change value directly

Immutable

- May change "behind scenes"
- **Example:** turtle.x
- Has only a getter
 - No setter means no change
 - Getter allows limited access

May ask you to differentiate on the exam
