

Linear Search

```
def linear_search(v,b):
    """Returns: first occurrence of v in b (-1 if not found)
    Precond: b a list of number, v a number
    """
    # Loop variable
    i = 0
    while i < len(b) and b[i] != v:
        i = i + 1
    if i == len(b): # not found
        return -1
    return i
```

How many entries do we have to look at?

All of them!

1

Binary Search

```
def binary_search(v,b):
    # Loop variable(s)
    i = 0, j = len(b)
    while i < j and b[i] != v:
        mid = (i+j)//2
        if b[mid] < v:
            j = mid
        elif b[mid] > v:
            i = mid
        else:
            return mid
    return -1 # not found
```

Requires that the data is sorted!

But few checks!

2

The Sorting Challenge

- **Given:** A list of numbers
- **Goal:** Sort those numbers using only
 - Iteration (while-loops or for-loops)
 - Comparisons (< or >)
 - Assignment statements
- Why? For proper **analysis**.
 - Methods/functions come with hidden costs
 - Everything above has no hidden costs
 - Each comparison or assignment is “1 step”

3

Horizontal Notation

- Want a pictorial way to visualize this sorting
 - Represent the list as long rectangle
 - We saw this idea in divide-and-conquer
- Do **not** show individual boxes
 - Just dividing lines between regions
 - Label dividing lines with indices
 - But index is either left or right of dividing line

4

Visualizing Sorting

5

Insertion Sort

```
i = 0
while i < n:
    # Push b[i] down into its
    # sorted position in b[0..i]
    i = i + 1
```

Remember the restrictions!

6

Insertion Sort: Moving into Position

```

i = 0
while i < n:
    push_down(b,i)
    i = i+1

def push_down(b, i):
    j = i
    while j > 0:
        if b[j-1] > b[j]:
            swap(b[j-1],j)
        j = j-1

```

swap shown in the lecture about lists

7

Insertion Sort: Performance

```

def push_down(b, i):
    """Push value at position i into
    sorted position in b[0..i-1]"""
    j = i
    while j > 0:
        if b[j-1] > b[j]:
            swap(b[j-1],j)
        j = j-1

```

- $b[0..i-1]$: i elements
- Worst case:
 - $i = 0$: 0 swaps
 - $i = 1$: 1 swap
 - $i = 2$: 2 swaps
- Pushdown is in a loop
 - Called for i in $0..n$
 - i swaps each time

Insertion sort is an n^2 algorithm

Total Swaps: $0 + 1 + 2 + 3 + \dots (n-1) = (n-1)*n/2 = (n^2-n)/2$

8

Algorithm "Complexity"

- **Given:** a list of length n and a problem to solve
- **Complexity:** rough number of steps to solve worst case
- Suppose we can compute 1000 operations a second:

Complexity	n=10	n=100	n=1000
$\log n$	0.003 s	0.006 s	0.01 s
n	0.01 s	0.1 s	1 s
$n \log n$	0.016 s	0.32 s	4.79 s
n^2	0.1 s	10 s	16.7 m
n^3	1 s	16.7 m	11.6 d
2^n	1 s	4×10^{19} y	3×10^{290} y

9

A New Algorithm

Start: b [0...n] ?

Goal: b [0...n] sorted

In-Progress: b [0...i] sorted, $\leq b[i..]$ $\geq b[0..i-1]$

First segment always contains smaller values

10

Selection Sort

b [0...i] sorted, $\leq b[i..]$ $\geq b[0..i-1]$

```

i = 0
while i < n:
    # Find minimum in b[i..]
    # Move it to position i
    i = i+1

```

Remember the restrictions!

11

What is the Problem?

- Both insertion, selection sort are **nested loops**
 - **Outer loop** over each element to sort
 - **Inner loop** to put next element in place
 - Each loop is n steps. $n \times n = n^2$
- To do better we must *eliminate* a loop
 - But how do we do that?
 - What is like a loop? **Recursion!**
 - Will see how to do this next lecture

12
