#### Previous lecture

- Finite/inexact arithmetic
- Plotting continuous functions using vectors and vectorized code
- User-defined functions
  - Function header

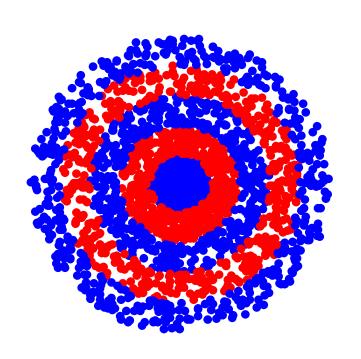

# Today's lecture

- User-defined functions
  - Input parameters and return variables
  - local memory space
  - Subfunction

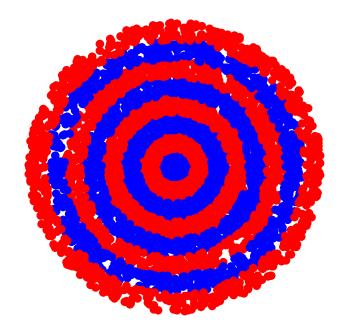

### Announcement

Prelim I tonight at 7:30pm Statler Auditorium

# Draw a bulls eye figure with randomly placed dots

- Dots are randomly placed within concentric rings
- User decides how many rings, how many dots

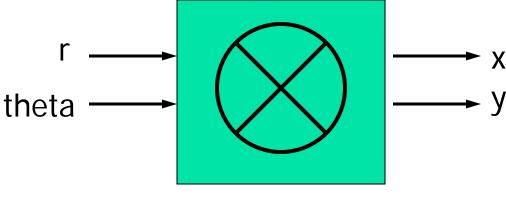

```
c= input('How many concentric rings? ');
d= input('How many dots? ');
% Put dots btwn circles with radii rRing and (rRing-1)
for rRing= 1:c
 % Draw d dots
 for count = 1:d
   % Generate random dot location (polar coord.)
   theta=____
   r=
   % Convert from polar to Cartesian
   x=____
   y=____
   % Use plot to draw dot
 end
end
```

```
c= input('How many concentric rings? ');
d= input('How many dots? ');
% Put dots btwn circles with radii rRing and (rRing-1)
for rRing= 1:c
  % Draw d dots
  for count= 1:d
    % Generate random dot location (polar coord.)
    theta=
    r=
    % Convert from polar to Cartesian
   rads= theta*pi/180;
                             A common task! Create a
    x= r*cos(rads);
   y= r*sin(rads);
                             function polar2xy to do
                             this. polar2xy likely
    % Use plot to draw dot
                             useful in other problems as
 end
                             well.
end
```

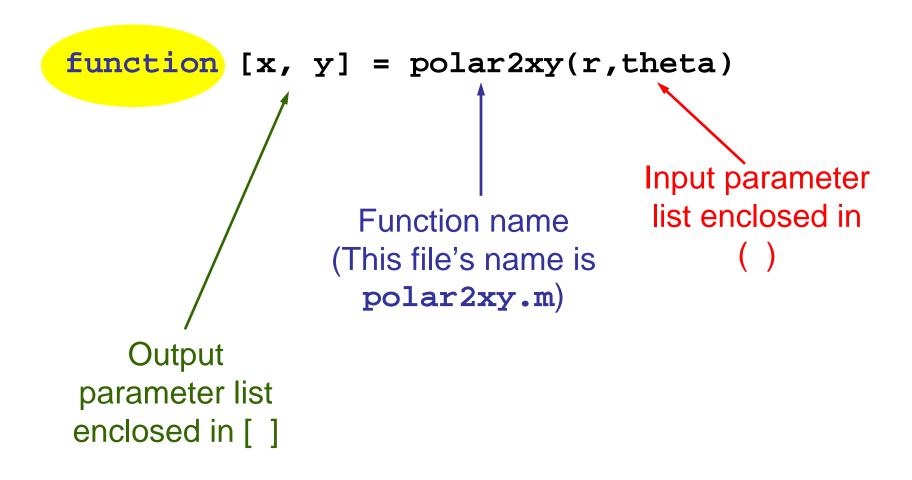

```
function [x, y] = polar2xy(r,theta)
% Convert polar coordinates (r,theta) to
% Cartesian coordinates (x,y).
% theta is in degrees.

rads= theta*pi/180; % radian
x= r*cos(rads);
y= r*sin(rads);
```

### Think of **polar2xy** as a factory

```
% Put dots btw circles with radii rRing and (rRing-1)
for rRing= 1:c
 % Draw d dots
 for count= 1:d
   % Generate random dot location
   theta=
   r=
   % Convert from polar to Cartesian
     y = r * s \dots
                      [x,y] = polar2xy(r,theta);
   % Draw the dot
 end
end
```

#### Function header is the "contract" for how the function will be used (called)

#### You have this function:

```
function [x, y] = polar2xy(r, theta)
% Convert polar coordinates (r, theta) to
% Cartesian coordinates (x,y). Theta in degrees.
...
```

### Code to call the above function:

```
% Convert polar (rl,tl) to Cartesian (xl,yl)
rl= l; tl= 30;
[xl, yl]= polar2xy(rl, tl);
plot(xl, yl, 'b*')
...
```

#### Function header is the "contract" for how the function will be used (called)

### You have this function:

```
function [x, y] = polar2xy(r, theta)

% Convey polar coording as ( theta) to

% Carte ( theta) to ( theta) in degrees.

...
```

# Code to all the above funtion:

```
% Conjert polar (rl,) ) Cartesian (xl,yl)
rl: | | tl = 30;
[xl, yl] = polar2xy(rl, tl);
plot(xl, yl, 'b*')
...
```

# Returning a value # printing a value

### You have this function:

```
function [x, y] = polar2xy(r, theta)
% Convert polar coordinates (r,theta) to
% Cartesian coordinates (x,y). Theta in degrees.
...
```

### Code to call the above function:

```
% Convert polar (rl,tl) to Cartesian (xl,yl)
rl= l; tl= 30;
[xl, yl]= polar2xy(rl, tl);
plot(xl, yl, 'b*')
```

# Returning a value \neq printing a value Function prints instead of returns values

# You have this function:

function [x, x] = polar2xy(r, theta)

- % Convert polar coordinates (r,theta) to

% Cartesian coordinates 
$$(x,y)$$
. Theta in degrees. ...  $fprintf((\%,1f,\%,1f)),(x,y)$ 

### Code to call the above function:

#### Given this function:

```
function m = convertLength(ft,in)
% Convert length from feet (ft) and inches (in)
% to meters (m).
. . .
```

How many proper calls to convertLength are shown below?

```
% Given f and n
d= convertLength(f,n);
d= convertLength(f*12+n);
d= convertLength(f+n/12);
x= min(convertLength(f,n), 1);
y= convertLength(pi*(f+n/12)^2);
A: 1
B: 2
C: 3
D: 4
E: 5 or 0
```

#### General form of a user-defined function

```
function [out I, out 2, ...] = functionName (in I, in 2, ...)
```

- % I-line comment to describe the function
- % Additional description of function

Executable code that at some point assigns values to output parameters out I, out 2, ...

- in I, in 2, ... are defined when the function begins execution.
  Variables in I, in 2, ... are called function parameters and they hold the function arguments used when the function is invoked (called).
- out 1, out 2, ... are not defined until the executable code in the function assigns values to them.

# dotsInCircles.m

```
(functions with multiple input parameters)
(functions with a single output parameter)
(functions with multiple output parameters)
(functions with no output parameter)
```

### Comments in functions

 Block of comments after the function header is printed whenever a user types

at the Command Window

Ist line of this comment block is searched whenever a user types

lookfor <someWord>

at the Command Window

 Every function should have a comment block after the function header that says what the function does concisely

# Accessing your functions

For now\*, put your related functions and scripts in the same directory.

dotsInCircles.m polar2xy.m

randDouble.m drawColorDot.m

Any script/function that calls polar2xy.m

\*The path function gives greater flexibility

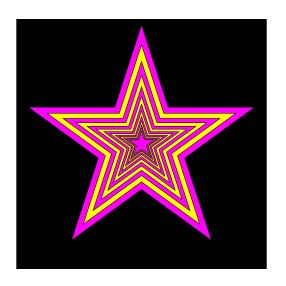

# Why write user-defined function?

- Easy code re-use—great for "common" tasks
- A function can be tested independently easily
- Keep a driver program clean by keeping detail code in functions—separate, non-interacting files

```
c= input('How many concentric rings? ');
d= input('How many dots? ');
% Put dots btwn circles with radii rRing and (rRing-1)
for rRing= 1:c
 % Draw d dots
 for count= 1:d
   % Generate random dot location (polar coord.)
   theta=
   r=
   % Convert from polar to Cartesian
   x= ____
   y=____
                                Fach task becomes a
                                function that can be
   % Use plot to draw dot
                                implemented and
 end
                                tested independently
end
```

# Facilitates top-down design

I. Focus on how to draw the figure given just a specification of what the function DrawStar does.

2. Figure out how to <u>implement</u> DrawStar.

# To specify a function...

... you describe how to use it, e.g.,

```
function DrawStar(xc,yc,r,c)
% Adds a 5-pointed star to the
% figure window. Star has radius r,
% center(xc,yc) and color c where c
% is one of 'r', 'g', 'y', etc.
```

Given the specification, the user of the function doesn't need to know the detail of the function—they can just use it!

# To <u>implement</u> a function...

... you write the code so that the function "lives up to" the specification. E.g.,

```
r2 = r/(2*(1+sin(pi/10)));
tau = pi/5;
for k=1:11
    theta = (2*k-1)*pi/10;
    if 2*floor(k/2) \sim = k
      x(k) = xc + r*cos(theta);
      y(k) = yc + r*sin(theta);
    else
      x(k) = xc + r2*cos(theta);
                                   Don't worry—you'll learn more about graphics
      y(k) = yc + r2*sin(theta);
    end
end
                                    functions soon.
fill(x,y,c)
```

# Why write user-defined function?

- Easy code re-use—great for "common" tasks
- A function can be tested independently easily
- Keep a driver program clean by keeping detail code in functions—separate, non-interacting files
- Facilitate top-down design
- Software management

# Software Management

# Today:

I write a function

EPerimeter(a,b)

that computes the perimeter of the ellipse

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$$

# Software Management

During this year:

You write software that makes extensive use of

EPerimeter(a,b)

Imagine hundreds of programs each with several lines that reference **Eperimeter** 

# Software Management

# Next year:

I discover a more efficient way to approximate ellipse perimeters. I change the implementation of

EPerimeter(a,b)

You do not have to change your software at all.

# Script vs. Function

- A script is executed line-byline just as if you are typing it into the Command Window
  - The value of a variable in a script is stored in the Command Window Workspace

- A function has its own private (local) function workspace that does not interact with the workspace of other functions or the Command Window workspace
  - Variables are not shared between workspaces even if they have the same name

```
% Script file
p= -3;
q= absolute(p);
disp(p)
```

```
function q = absolute(p)
% q is absolute value of p
if (p<0)
    p= -p;
end
q= p;</pre>
```

A: -3

B: 3

C: error

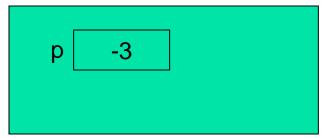

```
% Script file
p= -3;
q= absolute(p);
disp(p)
```

```
function q = absolute(p)
% q is the absolute value of p
if (p<0)
p= -p;
end
q= p;
```

```
% Script file
p= -3;
q= absolute(p);
disp(p)
```

```
function q = absolute(p)

end
q= p;</pre>
```

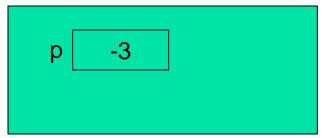

#### Command Window Workspace

### **REVIEW!!!**

% Script file

$$p = -3;$$

.q= absolute(p);

disp(p)

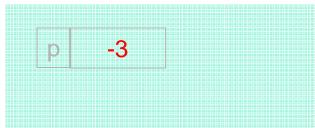

function q = absolute(p)

% q is the absolute value of p

end

A value is passed to the function parameter when the function is called.

Command Window Workspace

-3

Function The two variables, both called p, live in different memory space and do not interfere.

### **REVIEW!!!!**

% Script file p = -3;.q= absolut<del>e(p);</del> disp(p)

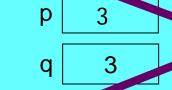

% q is the absolute returns the if (p<0)p = -p;end q = p;

When a function reaches the end function q = absolute of execution (and output argument), the function space local space—is deleted.

#### **Command Window Workspace**

#### Function absolute's Workspace

# What is the output?

```
x = 1;
x = f(x+1);
y = x+1;
disp(y)
```

```
function y = f(x)
x = x+1;
y = x+1;
```

# Subfunction

- There can be more than one function in an M-file
- top function is the main function and has the name of the file
- remaining functions are subfunctions, accessible only by the functions in the same m-file
- Each (sub)function in the file begins with a function header
- Keyword end is not necessary at the end of a (sub)function
