- Previous Lecture:
 - Examples on cell arrays, file I/O, sort
- Today's Lecture:
 - Structures
 - Structure array (i.e., an array of structures)
 - A structure with array fields
- Announcement:
 - Project 5 due tonight at 11pm
 - Review session Sunday 1-2:30pm, HLS B14
 - Prelim 2 on Tuesday 7:30pm

Data are often related

- A point in the plane has an x coordinate and a y coordinate.
- If a program manipulates lots of points, there will be lots of x's and y's.
- Anticipate clutter. Is there a way to "package" the two coordinate values?

Lecture 20

Packaging affects thinking

Our Reasoning Level:

P and Q are points.
Compute the midpoint M of the connecting line segment.

Behind the scenes we do

$$M_x = (P_x + Q_x)/2$$

 $M_y = (P_y + Q_y)/2$

We've seen this before: functions are used to "package" calculations.

This packaging (a type of abstraction) elevates the level of our reasoning and is critical for problem solving.

Lecture 20

Example: a Point structure

% p1 is a Point

p1.x = 3;

p1.y=4;

% p2 is another Point

p2.x= -1;

p2.y= 7;

3 4 y p1

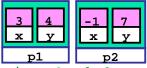

A Point has two properties—fields—x and y

Leeture 20

Working with Point structures

p1.x=3; p1.y=4; p2.x=-1; p2.y=7;

% Distance between points p1 and p2
D= sqrt((p1.x-p2.x)^2 + (p1.y-p2.y)^2);

Note that pl.x, pl.y, p2.x, p2.y participate in the calculation as variables—because they are.

Lecture 20

Different ways to create a structure

% Create a struct by assigning field values

p1.x= 3; p1.y= 4;

% Create a struct with built-in function

p2 = struct(x',-1, y',7);

p2 is a structure.

The structure has two fields.

Their names are x and y.

They are assigned the values -I and 7.

p1
-1 7
x y

Lecture 20

A structure can have fields of different types

- Can have combinations of string fields and numeric fields
- Arguments are given in pairs: a field name, followed by the value

ceture 20

Structures in functions

Example "Make" Function

```
function P = MakePoint(x,y)

% P is a point with P.x and P.y

% assigned the values x and y.

% assigned the values x and y.

function P = MakePoint(x,y)

% P is a point with P.x and P.y

% assigned the values x and y.

function P = MakePoint(x,y)

% P is a point with P.x and P.y

% assigned the values x and y.
```

Then in a script or some other function...

Another function that has structure parameters

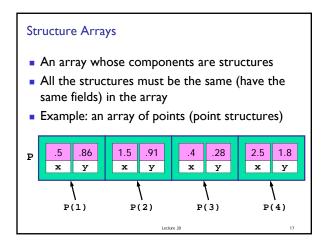

```
function DrawLine(P,Q,c)
% P and Q are points (structure).
% Draws a line segment connecting
% P and Q. Color is specified by c.
plot([P.x Q.x],[P.y Q.y],c)
```

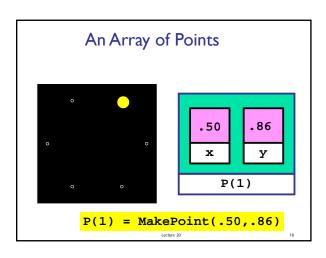

Pick Up Sticks

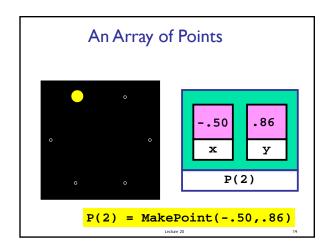

```
s = 'rgbmcy';
for k=1:100
   P = MakePoint(randn,randn);
   Q = MakePoint(randn,randn);
   c = s(ceil(6*rand));
   DrawLine(P,Q,c)
end
```

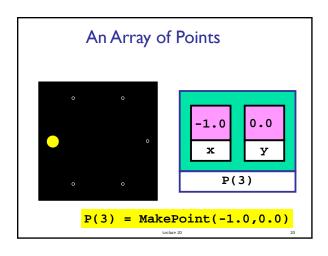

Generates two random points and connect them using one of six colors chosen randomly.

ure 20

Function returning an array of points (point structures)

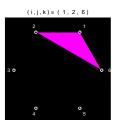

function P = CirclePoints(n)
%P is array of n point structs; the
%points are evenly spaced on unit circle

theta = 2*pi/n;
for k=1:n
 c = cos(theta*k);
 s = sin(theta*k);
 P(k) = MakePoint(c,s);
end

Example: all possible triangles

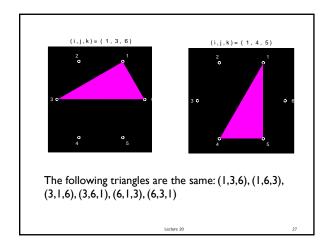

- Place n points uniformly around the unit circle.
- Draw all possible unique triangles obtained by connecting these points 3-at-a-time.

3

```
function DrawTriangle(U,V,W,c)
% Draw c-colored triangle;
% triangle vertices are points U,
% V, and W.
fill([U.x V.x W.x], ...
[U.y V.y W.y], c)
```

```
Bad! i, j, and k should be different, and
there should be no duplicates

% Given P, an array of point structures
for i=1:n
for j=1:n
for k=1:n
DrawTriangle(P(i),P(j),P(k),'m')
pause
DrawTriangle(P(i),P(j),P(k),'k')
end
end
end
end
```

```
All possible (i,j,k) combinations but avoid duplicates.
 Loop index values have this relationship i < j < k
   i j k
   123
                234
   124
                2 3 5
                             3 4 6
   125
                236
                             3 5 6
   126
                2 4 5
                            i = 3
   134
                246
                              for i=1:n-2
   1 3 5
                256
                                for j=i+1:n-1
   136
                                  for k=j+1:n
               i = 2
   145
                                    disp([i j k])
                                  end
   146
                                end
                               end
  i = 1
```

```
All possible (i,j,k) combinations but avoid duplicates.

Loop index values have this relationship i < j < k

for i=1:n-2

for j=i+1:n-1

for k=j+1:n

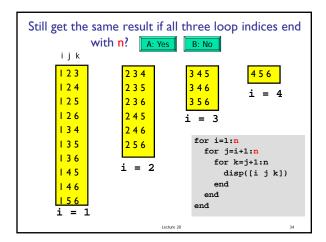

% Draw triangle with
% vertices P(i),P(j),P(k)

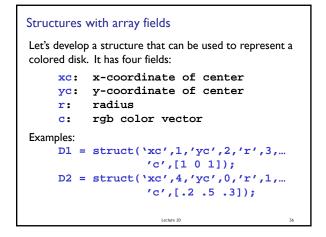

end
end
end
end
```

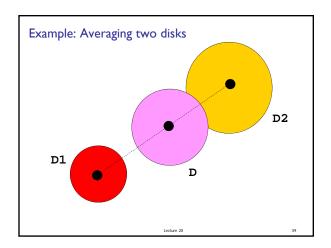

```
All possible triangles

% Drawing on a black background
for i=1:n-2
for j=i+1:n-1
for k=j+1:n

DrawTriangle( P(i),P(j),P(k),'m')
DrawPoints(P)
pause
DrawTriangle(P(i),P(j),P(k),'k')
end
end
end
```

Example: compute "average" of two disks

% D1 and D2 are disk structures.

% Average is:

r = (D1.r + D2.r) /2;

xc = (D1.xc + D2.xc)/2;

yc = (D1.yc + D2.yc)/2;

c = (D1.c + D2.c) /2;

% The average is also a disk

D = struct('xc',xc,'yc'yc,'r',r,'c',c)

```
How do you assign to g the green-color component of disk D?

D= struct('xc',3.5, 'yc',2, ... 'r',1.0, 'c',[.4 .1 .5])

A: g = D.g;

B: g = D.c.g;

C: g = D.c.2;

D: g = D.c(2);

E: other
```

```
A structure's field can hold a structure

A = MakePoint(2,3)
B = MakePoint(4,5)
L = struct('P',A,'Q',B)

This could be used to represent a line segment with endpoints P and Q, for instance
Given the MakePoint function to create a point structure, what is x below?

x = L.P.y;

A: 2
B: 3
C: 4
D: 5
E: error
```
