CS113: Lecture 2

Topics:

- Decision and Control statements (e.g. if-else, switch, while, etc.)
- Relational, Equality, and Logical operators

if statement

- Basic form:

```
if( condition )
   statement;
```

(Statement executed if, and only if, the condition is "true")

- Example (fragment):

```
if( 5 > 3 )
   printf( "5 is strictly greater than 3.\n" );
```

- The `statement` can be a block of code containing more than one statement - enclosed in curly braces:

```
if( a > 0 ) {
   printf( "a is positive.\n" );
   printf( "In case you didn't hear me,
            I said that a is positive.\n" );
}
```

- Be careful! What happens here?

```
a = -5;
if( a > 0 )
   printf( "a is positive.\n" );
   printf( "In case you didn't hear me,
            I said that a is positive.\n" );
```

Relational and Equality operators

- In actuality, expressions like "5 $>$ 3" are evaluated to integer values: 1 for true, 0 for false. Thus the program

```
void main() {
   printf( "Result of 1 > 2: %d\n", 1 > 2 );
   printf( "Result of 6 < 8: %d\n", 6 < 8  );
}
```

  gives as output:

```
Result of 1 > 2: 0
Result of 6 < 8: 1
```

- Relational operators: `>`, `>=`, `<`, `<=`

- Equality operators: `==`, `!=`
  - IMPORTANT! `==` (two equals) versus `=` (one equal) is an extremely common source of programmer errors in C. One equal, `=`, is an assignment operator.

More on our friend if

- if executes the statement (or statement block) after it when the specified condition is non-zero.

- Thus, the following fragment prints: `Hi!`

```
if( 18 )
   printf( "Hi!\n" );
if( 0 )
   printf( "Bye.\n" );
```

- What does the following fragment do?

```
int a;
printf( "Enter a number:" );
scanf( "%d", &a );
if( a = 3 )
   printf( "You typed 3.\n" );
```

- Notice that there is no semicolon after the condition of an `if` statement.

Conditional Expressions

Consider the following code:

```
if (a < 13)
  b = 3;
else
  b = 18;
```

C has a construct that lets you encapsulate the choice as part of the expression assigned to the variable `b`. The following code is equivalent:

```
b = (a < 13) ? 3 : 18;
```

The general form is `test ? expr1 : expr2`. The test `test` is evaluated first. If it is nonzero, the entire expression evaluates to `expr1`, otherwise it evaluates to `expr2`.

Since the whole term is itself an expression, we can nest conditional expressions:

```
grade = (percent > 80) ? 'A' :
        ((percent > 70) ? 'B' : 'C');
```

Logical Operators

- Enter the three logical operators: `&&`, `||`, `!`
- `&&`, `||` (logical AND, logical OR) are binary operators: two arguments.
- `expression1 && expression2` evaluates to 1 ("true") if both expressions are non-zero, otherwise evaluates to 0 ("false").
- `expression1 || expression2` evaluates to 1 ("true") if either or both expressions are non-zero, otherwise evaluates to 0 ("false").
- `!expression` evaluates to 1 ("true") if the expression is zero, otherwise evaluates to 0 ("false").
- Example.

```
if(( 3 >= 5 ) || !(2 > 4)) {
   printf( "The OR is true.\n" );
}
if(( 3 >= 5 ) && !(2 > 4)) {
   printf( "The AND is true.\n" );
}
```

- "Short-circuit evaluation" used.

  (The `!(2 > 4)` in second `if` not evaluated.)

if-else

- Basic form:

```
if( condition )
   statement1;
else
   statement2;
```

- As before, each `statement` can be either a single command (terminated with a semicolon), or a block of commands delimited by curly braces.

- Example.

```
if(( year % 4 == 0  &&  year % 100 != 0 ) ||
   ( year % 400 == 0 )) {
   printf( "%d is a leap year\n", year );
} else {
   printf( "%d is not a leap year\n", year );
}
```

More on if-else

- Is there a difference between

```
if( condition )
   statement1;
else
   statement2;
```

and

```
if( !condition )
   statement2;
else
   statement1;
```

- Common usage for a series of if-elses:

```
if( expression1 )
   statement1;
else if( expression2 )
   statement2;
else if( expression3 )
   statement3;
...
else
   statement;
```

The temptation is to continually indent.

Under what conditions is `statement3` executed?

An example

- Example.

```
void main() {
   int num;
   printf( "Please enter a positive integer:\n" );
   scanf( "%d", &num );

   if( num % 3 == 0 )
      printf( "%d is divisible by 3.\n", num );
   else if( num % 2 == 0 )
      printf( "%d is divisible by 2, but not 3.\n",
              num );
   else
      printf( "%d is not divisible by 3 nor 2.\n",
              num );
}
```

The "dangling else problem"

- The following code is ambiguous. Never write anything like this!

```
if( a == 3 )
if( a == 5 )
   printf( "a is 5.\n" );
else
   printf( "Doh!\n" );
```

- Instead, use braces:

```
if( a == 3 ) {
   if( a == 5 )
      printf( "a is 5.\n" );
   else
      printf( "Doh!\n" );
}
```

switch statement

- Similar to a chain of if/else statements, but more restricted in terms of functionality.

- Useful when one wants to branch based on the value of an expression.

- General form:

```
switch( expression ) {
   case constant1:
      statement1;
      [break;]
   case constant2:
      statement2;
      [break;]
   ...
   default:
      statement;
      [break;]
}
```

The fall-through property

- Use breaks! What happens if the breaks are removed?

```
switch( num ) {
   case 1:
      printf( "Behind Door 1 is nothing.\n" );
      break;
   case 2:
      printf( "Behind Door 2 is a goat.\n" );
      break;
   case 3:
      printf( "Behind Door 3 is a pot of gold.\n" );
      break;
}
```

- Sometimes we can exploit the fall-through property:

```
switch( month ) {
   case 1: case 3: case 5: case 7:
   case 8: case 10: case 12:
      printf( "31 days.\n" );
      break;
   case 2:
      printf( "28 or 29 days.\n" );
      break;
   default:
      printf( "30 days.\n" );
}
```

while statement

- Nice and simple:

```
while( condition )
   statement;
```

- A `break` statement inside the statement block causes the loop to be stopped.

- A variant:

```
do
   statement;
while( expression );
```

- The statement is always executed at least once. Equivalent to:

```
statement;
while( expression )
   statement;
```

while example

- Keeping a running sum.

```
void main() {
   int sum = 0, number = 0;
   while( number != -1 ) {
      sum += number;
      printf( "The running sum is: %d\n", sum );
      printf( "Enter a pos. integer (-1 quits):" );
      scanf( "%d", &number );
   }
}
```

- Another way to do it.

```
void main() {
   int sum = 0, number;
   while( 1 ) {
      printf( "The running sum is: %d\n", sum );
      printf( "Enter a pos. integer (-1 quits):" );
      scanf( "%d", &number );
      if( number == -1 ) break;
      sum += number;
   }
}
```

Note: `while( 1 )` is conventional for "infinite" loops

for statement

- General form:

```
for( initial-stmt; condition; iteration-stmt )
   body-stmt;
```

- Equivalent to:

```
initial-stmt;
while( condition ) {
   body-stmt;
   iteration-stmt;
}
```

- `break` can also be used, within the `body-stmt`.

- `break` in general applies to innermost loop (while, do/while, for) or switch statement.

- `continue` statement (not frequently used) causes the next iteration to be executed - jumps to condition-test of innermost loop (while, do/while) or next increment statement (for).

for example

- Summing the first ten positive even numbers (2, 4, 6, ..., 20).

```
void main() {
   int i, sum = 0;
   for( i = 1; i <= 10; i++ )
      sum += 2 * i;
   printf( "The sum is %d\n", sum );
}
```

- Another way to do it.

```
void main() {
   int i, sum = 0;
   for( i = 2; i <= 20; i += 2 )
      sum += i;
   printf( "The sum is %d\n", sum );
}
```

- Notice: no semicolon after the condition of the `for`.
