#### Processes vs. Threads

#### Processes . . .

- Multiple simultaneous programs
- Independent memory space
- Independent open file-descriptors

#### Threads . . .

- Multiple simultaneous functions
- Share the same memory
- Share the same open file-descriptors

# Threads Examples

- Graphical User Interfaces (GUIs)
  - ► The GUI is usually put on a separate thread from the "app engine"
  - GUI remains responsive even if app blocks for processing
- Web Browser Tabs
  - Each tab is managed by a separate thread for rendering
  - Web pages render "simultaneously"
  - Note: Google Chrome actually uses a separate process per tab

### **Threads**

- One copy of the heap
- ▶ One copy of the code
- Multiple stacks

### **Threads**

```
#include <pthread.h>
void *main2(void *arg) {
    . . .
void *main1(void *arg) {
    . . .
int main() {
    pthread_t id1, id2;
    pthread_create(&id1, NULL, main1, NULL);
    pthread_create(&id2, NULL, main2, NULL);
    . . .
... think multiple processors (or cores)
```

# pthread

### Starting a thread

```
#include <pthread.h>
pthread_t id;
err = pthread_create(&id, NULL, entry_func, arg);
Body of a thread
void *entry_func(void *arg) {
      . . .
Exiting current thread
      pthread_exit((void *)return_value);
```

## pthread

```
Co-operative Multi-Threading on Single Processor
#include <sched.h>
...
sched_yield()
```

- Store stack pointer, internal state etc. for current thread
- Restore stack pointer, internal state etc. for another thread
- Resume executing other thread

From the caller's perspective, sched\_yield() blocks until the other thread calls sched\_yield(). Allows multiple threads to share the CPU cooperatively.

# pthread

### Non-Cooperative Multi-Threading

Thread library (pthread) pre-empts thread when it invokes an OS function.

- Almost transparent when writing code
- Whole new class of bugs: Concurrency bugs
  - Multiple threads accessing same object concurrently
  - Solution: Locks only one thread can grab lock
