**Lecture 13: Generic Programming and Inner
Classes**

Announcements

- Assignment 3 Programming due today
- Assignment 3 Written due tomorrow
- Slight schedule change: Generic Programming today, ADTs Wednesday and Thursday
- Quiz Friday on Complexity, Iterators, and ADTs
- Prelim 2 next Wednesday
- Reading for today: Weiss 6.1-6.4

Linear Search

- First version:
 - Input was `int[]`, used `==` to compare elements
- More generic version:
 - Input was `Comparable[]`, used `compareTo()`
- Is there a *still more* generic version that is independent of the data structure?
 - For example, works even with `Comparable[][]`

Key Ideas

- **Iterator** interface
- Linear search written once and for all using **Iterator** interface
- Any data structure that wants to support linear search must implement **Iterator**
- Implementing **Iterator** interface
 - We will look at three implementations
 - Anonymous inner classes provide an elegant solution

Linear Search

```
boolean linearSearch(Comparable[] a, Object v) {  
    for (int i = 0; i < a.length; i++) {  
        if (a[i].compareTo(v) == 0) return true;  
    }  
    return false;  
}
```

- relies on data being stored in a 1D array
- will not work if data is stored in another data structure such as a 2D array, list, stack, queue, ...

Linear Search

```
boolean linearSearch(Comparable[] a, Object v) {  
    for (int i = 0; i < a.length; i++) {  
        if (a[i].compareTo(v) == 0) return true;  
    }  
    return false;  
}
```

All linear search needs to know is:

1. are there more elements to look at?
2. if so, get me the next element

Generic Linear Search

- Data is contained in some object
- Object has an **adapter** that permits data to be enumerated in some order
- Adapter has two buttons
 - **boolean hasNext()**: are there more elements to be enumerated?
 - **Object next()**: if so, give me a new element that has not been enumerated so far

Iterator Interface

```
interface Iterator {  
    boolean hasNext();  
    Object next();  
    void remove(); //we will not use this  
}
```

```
interface Iterable {  
    Iterator iterator();  
}
```

- predefined in Java
- linear search can be written using **Iterator** interface
- any data class that wishes to allow searching using this code can do so by implementing **Iterable** (i.e., by providing an **Iterator**)

Enumeration Interface

```
interface Enumeration {  
    boolean hasMoreElements();  
    Object nextElement();  
}
```

- similar functionality to **Iterator** (no **remove** method)
- **Iterator** is preferred

Generic Linear Search

Array version

```
boolean linearSearch(Object[] a, Object v) {  
    for (int i = 0; i < a.length; i++) {  
        if (a[i].equals(v)) return true;  
    }  
    return false;  
}
```

Iterator version

```
boolean linearSearch(Iterator a, Object v) {  
    while (a.hasNext()) {  
        if (a.next().equals(v)) return true;  
    }  
    return false;  
}
```

Note: `public boolean equals(Object obj)` must be implemented properly (overridden in the class which is the dynamic type of `a`) properly for this to work.

How Do You Produce an Iterator?

Some possibilities:

1. Adapter is a separate class from the data class
2. Adapter is an **inner class** of the data class
3. Adapter is an **anonymous** inner class

Adapter (Version 1)

```
class ArrayIterator implements Iterator {  
    private Object[] data;  
    private int index = 0; //index of next element  
  
    public ArrayIterator(Object[] a) {  
        data = a;  
    }  
    public boolean hasNext() {  
        return (index < data.length);  
    }  
    public Object next() {  
        return data[index++];  
    }  
}
```

Using the Adapter

```
String[] a = {"Hello", "world"};

Iterator iter = new ArrayIterator(a);
while (iter.hasNext()) {
    System.out.println(iter.next());
}

iter = new ArrayIterator(a);
if (linearSearch(iter, "world")) {
    System.out.println("found!");
}
```

Features

- Can create as many iterators as needed
- Works for other data structures
 - 2D arrays: keep two cursors, one for row, one for column
 - standard orders of enumeration:
 - row-major
 - column-major

```
class Array2DIterator implements Iterator {
    private Object[][] data;
    private int rowIndex = 0, colIndex = 0;

    public Array2DIterator(Object[][] a) { data = a; }

    public boolean hasNext() {
        while (rowIndex < data.length
            && colIndex >= data[rowIndex].length) {
            rowIndex++; colIndex = 0; //if end of row
        }
        return (rowIndex < data.length
            && colIndex < data[rowIndex].length);
    }

    public Object next() {
        if (hasNext()) return data[rowIndex][colIndex++];
        else throw new NoSuchElementException();
    }
}
```

Sharks and Remoras

Iterator implementation

is like a remora

Data class is like shark

A single shark must allow many remoras to hook to it

```
class Shark implements Iterable {  
    public Object[] data;  
    public Shark(Object[] a) { data = a; }  
    public Iterator iterator() {  
        return new Remora(this);  
    }  
}  
  
class Remora implements Iterator {  
    private int index = 0;  
    private Shark shark;  
    public Remora(Shark s) { shark = s; }  
    public boolean hasNext() {  
        return (index < shark.data.length);  
    }  
    public Object next() {  
        return shark.data[index++];  
    }  
}
```

Remora teeth

Client Code

```
String[] a = {"Hello", "world"};  
Shark s = new Shark(a); //object containing data  
boolean b = linearSearch(s.iterator(), "Hello");  
boolean c = linearSearch(s.iterator(), "world");  
boolean d = linearSearch(s.iterator(), "Bye");
```

Shark

Critique

- Good:
 - Shark class focuses on data, Remora class focuses on enumeration
- Bad:
 - Remora code relies on being able to access Shark variables such as **data** array
 - What if **data** was declared private?
 - Remora is specialized to Shark, but code appears outside Shark class
 - 2D array Shark will require a different Remora
 - We may change Shark class and forget to update Remora
 - Clients can create Remoras without invoking **iterator()** method of Shark
 - Better to have language construct to enforce convention

Better: Inner Classes

- Inner class: Java allows you declare a class within another class
- Inner classes can occur at many levels within another class
 - Member level
 - Inner class defined as if it were another field or method
 - Statement level
 - Inner class defined as if it were a statement in a method
 - Expression level
 - Inner class defined as it were part of an expression
 - Called anonymous classes
- Let us focus on member-level inner classes

Example of an Inner Class

```
class Shark implements Iterable {  
    public Object[] data;  
    public Shark(Object[] a) { data = a; }  
    public Iterator iterator() {  
        return new Remora();  
    }  
    class Remora implements Iterator {  
        private int index = 0;  
        public boolean hasNext() {  
            return (index < data.length);  
        }  
        public Object next() {  
            return data[index++];  
        }  
    }  
}
```

Client
Code

```
String[] a = {"Hello", "world"};  
Shark s = new Shark(a);  
boolean b = linearSearch(s.iterator(), "Hello");
```

Observations

- Inner class can be declared public, private, or protected
 - Inner class name is visible accordingly
- Inner class can also be instantiated by **outerObject.new InnerClass()**
 - e.g., **Shark.new Remora()**
 - but **new Shark.Remora()** does not work
- Instances of inner class have access to all members of containing outer class instance, even if declared private

- Keyword **this** in Remora class refers to Remora object, not outer Shark object
- How do we get a reference to Shark object from Remora? Here's one way:

```
class Shark {  
    private kahuna;  
    public Shark() { kahuna = this; }  
  
    class Remora{ //inner class  
        ...kahuna... //inner class simply accesses variable  
    }  
}
```

Adapter Classes

- An inner class is like an adapter that permits client code to work with class containing data without modifying the data class itself
- This is a very general design pattern that shows up in many contexts (e.g., GUI's)
- To permit programmers to write adapters compactly, Java permits programmers to write **anonymous classes**
 - Class does not have a name
 - Must be instantiated at the point where it is defined

Anonymous Classes

```
class Shark implements Iterable {  
    public Object[] data;  
    public Shark(Object[] a) { data = a; }  
    public Iterator iterator() {  
        return new Remora();  
    }  
    class Remora implements Iterator {  
        private int index = 0;  
        public boolean hasNext() {  
            return (index < data.length);  
        }  
        public Object next() {  
            return data[index++];  
        }  
    }  
}
```

Anonymous Classes

```
class Shark implements Iterable {  
    public Object[] data;  
    public Shark(Object[] a) { data = a; }  
    public Iterator iterator() {  
        return new Remora();  
    }  
    class Remora implements Iterator {  
        private int index = 0;  
        public boolean hasNext() {  
            return (index < data.length);  
        }  
        public Object next() {  
            return data[index++];  
        }  
    };  
}
```

Anonymous Classes

```
class Shark implements Iterable {  
    public Object[] data;  
    public Shark(Object[] a) { data = a; }  
    public Iterator iterator() {  
        return new Iterator {  
            private int index = 0;  
            public boolean hasNext() {  
                return (index < data.length);  
            }  
            public Object next() {  
                return data[index++];  
            }  
        };  
    }  
}
```

Anonymous Classes

- Class declaration has usual body, but
 - inner class
 - no name
 - no access specifier: public/private/protected
 - no explicit extends or implements
 - it either extends one class or implements one interface
 - no constructor

Creating an Instance of Anonymous Class A

- To specify that A extends superclass P
 - `new P { ... }; //creates instance of A`
 - `new P(42) { ... }; //calls a different constructor of P`
 - `P x = new P { ... }; //assignment`
- To specify that A implements interface I
 - `new I { ... }`
 - `I foo = new I { ... }; //assignment`
- Anonymous class can override methods of superclass P or implement interface methods of I
- All other methods and fields are effectively private
 - No way to invoke them from outside!

Conclusions

- Generic code
 - works on data collections without regard to type of elements or data structure
- Writing generic code
 - **Iterator** interface is very useful
 - use inner classes to implement it
