CS/ENGRD2110: Final Exam — SOLUTION

December 5, 2012

NAME :			
NETID:			
• The exaluck!	am is closed book and closed notes . Do not begin until instructed. Yo	u have 2.5]	hours. Good
• Start by writing your name and Cornell netid on top! There are 14 numbered pages . Check now that you have all the pages.			
• Web, email, etc. may not be used. Calculator with programming capabilities are not permitted—no calculators should be needed anyway. This exam is individual work .			
• We have scrap paper available, so you if you are the kind of programmer who does a lot of crossing out and rewriting, you might want to write code on scrap paper first and then copy it to the exam, just so that we can make sense of what you handed in!			
• Write your answers in the space provided. Ambiguous answers will be considered incorrect. You should be able to fit your answers easily into the space we provided . Answers that are not concise might not receive full points.			
• In some places, we have abbreviated or condensed code to reduce the number of pages that must be printed for the exam. In others, code has been obfuscated to make the problem more difficult. This does not mean that it's good style.

TOTAL

_____ / 136

1 Java Classes, Methods, and Types

1. Answer the following questions with either **True** or **False**. No explanation is necessary.

9 pts.

- When a method is invoked, the number of actual arguments and the compile-time types of the arguments are used, at compile time, to determine the signature of the method that will be invoked.
- If the method that is to be invoked is an instance method, the actual method to be invoked will be determined at run time, using dynamic method lookup.
- A constructor may be made abstract to specify a constructor signature in the extending class.
- Private member variables can be accessed directly by any extending classes.
- The following code will compile:

```
class Privy {
    private int hidden = 1;
}
class Child extends Privy {
    Child() { hidden = 2; }
}
```

• The following code will compile:

```
class Privy2 {
   private int hidden = 1;

   class Child2 extends Privy2 {
      Child2() { hidden = 2; }
   }
}
```

• The following code will compile but will generate a runtime exception:

```
ArrayList<?> magic = new ArrayList<Double>();
magic.add(new Double(5.0));
```

- Evaluating "1/0" will generate a runtime exception in Java.
- The only primitive types in Java are int, long, float, double, boolean, void, short, char

SOLUTION:

true

true

false

false

```
false (doesn't compile)
true (does compile)
false (doesn't even compile)
false (just a NaN)
false (missing byte)
END SOLUTION
```

2. The following program compiles and runs. What do each of the 10 calls to f in the main method print out? Write each answer to the right of the function call.

10 pts.

```
public static class MethodResolution
   static void println(String s) { System.out.println(s);}
   static interface Yum {
     public void f(Food x);
   static abstract class Food {
     public void f(Food x) { println("Eat something"); }
   static class Plum extends Food implements Yum {
     public void f(Banana x) { println("Jerry, eat a plum"); }
     public void f(Plum x) { println("Eat 2 plums"); }
   static class Banana extends Food implements Yum {
     public void f(Banana x) { println("Eat a banana"); }
   static class Sun extends Food implements Yum {
     public void f(Food x) { println("Vitamin D!"); }
     public void f(Yum x) { println("Yum"); }
  public static void main(String[] args) {
     Plum p = new Plum();
     Banana b = new Banana();
          s = new Sun();
     Yum yb = (Yum)b;
     Food fp = (Food)p;
     Food fb = (Food)b;
     p.f(b);
     p.f(fb);
     p.f(p);
     b.f(p);
     yb.f(b);
     b.f(b);
      fp.f(fp);
```

```
fp.f(b);
s.f(fp);
s.f(yb);
}}
```

SOLUTION:

Jerry, eat a plum

Eat something

Eat 2 plums

Eat something

Eat something

Eat a banana

Eat something

Eat something

Vitamin D!

Yum

END SOLUTION

2 Lists, Stacks, and Friends

1. Answer the following questions with either **True** or **False**. No explanation necessary.

3 pts.

- Stack operations (push, pop, is Empty) can be worst-case O(1) for a linked list implementation.
- Stack operations (push, pop, is Empty) can be worst-case O(1) for an array list implementation using a circular buffer.
- Enqueueing and dequeueing operations are all more expensive (worst case) for a priority queue backed by a balanced heap, than for a regular queue backed by a linked list.

SOLUTION:

true

false

true

END SOLUTION

- 2. (Similar to Carrano Ch6Ex10) Suppose that instead of doubling the size of an array-based stack when it becomes full, you increase the array size by the following sequence k, 2k, 3k, 4k, ... for some positive constant k.
 - (a) If you have an empty stack that uses an array whose initial size is k, and you perform n pushes (assume that n > k), how many resize operations will be performed?

3 pts.

SOLUTION:

 $\lfloor \frac{n}{k} \rfloor$ resizes are required

END SOLUTION

(b) What is the total cost complexity of executing n push operations? Explain your reasoning.

5 pts.

SOLUTION:

Assume the cost of expanding from k to 2k has 2k cost. To perform $\lfloor \frac{n}{k} \rfloor$ resizes has cost,

$$Cost = 2k + 3k + \dots + \left(\left\lfloor \frac{n}{k} \right\rfloor + 1\right)k \tag{1}$$

$$= 2k + 3k + ... + Nk (2)$$

$$= \left(\frac{N(N+1)}{2} - 1\right)k\tag{3}$$

$$= O(N^2k) (4)$$

$$= O(\frac{n^2}{k^2}k) \tag{5}$$

$$= O(\frac{n^2}{k}) \tag{6}$$

END SOLUTION

3. **Stack-Queue-List Jamboree:** Given the usual Java interfaces for Stack, Queue, and List, consider the following program:

```
import java.util.*;
public class Jamboree
  public static void main(String[] args)
                        S = new Stack<Integer>();  // push(I), pop()
     Stack<Integer>
                         Q = new LinkedList<Integer>(); // offer(I), poll()
      Queue<Integer>
      LinkedList<Integer> L = new LinkedList<Integer>();
      int[] examJoy = {5,3,4,1,2};
      for (int i=0; i<5; i++) {
         int x = examJoy[i];
         if(i%2==0)
           L.addFirst(x);
         else
           S.push(x);
      }
      while(!S.isEmpty() || !L.isEmpty()) {
         if(!S.isEmpty()) Q.offer(S.pop());
                                                                  //enqueue
         if(!L.isEmpty()) Q.offer(L.removeLast());
                                                                  //enqueue
         if(!Q.isEmpty()) System.out.println("Joy is "+Q.poll()); //dequeue
     }
   }
}
```

(a) The program compiles, and you run it. What is printed out?

5 pts.

```
SOLUTION:
```

Joy is 1

Joy is 5

Joy is 3

END SOLUTION

(b) What would be printed if Q were replaced by a "new PriorityQueue<Integer>()" (whose poll() returns the smallest enqueued item)?

5 pts.

SOLUTION:

Joy is 1

Joy is 3

Joy is 2

END SOLUTION

3 Trees

1. Answer the following questions with either **True** or **False**. No explanation necessary.

5 pts.

- A binary search tree with n integer entries can be searched in worst case time $O(\log n)$.
- In the tree below, nodes 5 and 2 are ancestors of 3.
- In the tree below, node 2 is at depth 2.
- In the tree below, nodes 0, 1 and 3 are siblings.
- In the tree below, node 5 is at height 2.

SOLUTION:

false

false

false

false

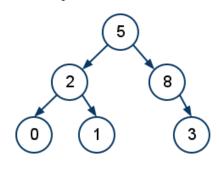

true

END SOLUTION

2. Consider the following TreeNode class, and the binary tree example:

```
public class TreeNode
{
  public TreeNode left;
  public TreeNode right;
  public Integer value;

  public TreeNode(int value) {
    this.value = new Integer(value);
  }
}
```

• Implement a recursive TreeNode method that counts the number of times a value occurs in the subtree rooted at that node. Let this TreeNode method have the following signature:

6 pts.

```
int count(int value) {
```

SOLUTION:

int n = 0; if(this.value.equals(value)) n++; if(left != null) n += left.count(value); if(right != null) n += right.count(value); return n;

END SOLUTION

• Report the pre-order traversal of the example tree, including null for missing children, that would be used, e.g., to write the tree to disk.

5 pts.

SOLUTION:

5, 2, 0, null, null, 1, null, null, 8, null, 3, null, null

END SOLUTION

4 Dictionaries and Hashtables

1. Answer the following questions with either **True** or **False**. No explanation necessary.

6 pts.

- The worst-case complexity of checking for an object in a hash set, i.e., contains (x), is O(1)
- The worst-case complexity of finding a key in a hash table with n entries is $O(\lambda)$ where λ is the load factor.
- For a hash table of size 5, the function "x % 5" maps the values {20, 6, 18, 14} to indices without collisions.
- For hash tables with linked-list chaining, the *load factor* λ corresponds to the fraction of buckets in the hash table that are not empty.
- Hash tables with linear probing only work for $\lambda \leq 1$.
- Hash tables with linked-list chaining only work for $\lambda \leq 1$.

SOLUTION:

false

false

true

false

true false

END SOLUTION

5 Graphs and Search

1. Answer the following questions with either **True** or **False**. No explanation necessary.

2 pts.

- Minimum spanning trees can be colored with only two colors.
- Dijkstra's algorithm is asymptotically faster than Prim's algorithm.

SOLUTION:

true

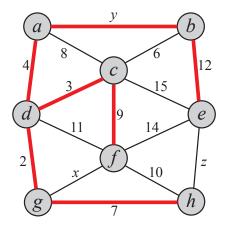

false

END SOLUTION

2.

MST Mystery: Consider the following graph with integer edge weights, some of which are unknowns indicated by x, y, and z. The minimum spanning tree (MST) is also drawn on the graph using bold lines. Use what you know about MST algorithms to infer what the missing edge weights could be in order for the MST to be as shown. If you cannot determine the integer weights exactly, state inequality bounds on x, y and z.

6 pts.

SOLUTION:

 $y \le 6$

 $z \ge 12$

END SOLUTION

3. **For the Swarm!** The order in which certain Zerg structures are built in *StarCraft 2* (the "Zerg Tech Tree") can be specified as an DAG (with unweighted edges) in adjacency matrix form:

Hatchery --> SpawningPool, EvolutionChamber

SpawningPool --> Lair, SpineCrawler, HydraliskDen, BanelingNest

EvolutionChamber --> SporeCrawler

Lair --> RoachWarren, InfestationPit, Spire

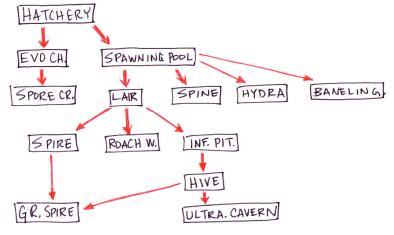

Spire --> GreaterSpire

InfestationPit --> Hive

Hive --> UltraliskCavern, GreaterSpire

• Draw the DAG (you can use shortened names if you wish, e.g., IP for InfestationPit) SOLUTION:

5 pts.

END SOLUTION

• Is this "Zerg tech tree" a tree? Why?

2 pts.

SOLUTION:

No, it is not a tree since there is a node (GreaterSpire) with more than one parent. END SOLUTION

• What is the *shortest* path from Hatchery to GreaterSpire? If it is nonunique, report all shortest paths. Report each "build order" in the form "Hatchery, Node2, ..., GreaterSpire."

6 pts.

SOLUTION:

HATCHERY, SPAWNING POOL, LAIR, SPIRE, GREATER SPIRE

Aside: This is just a shortest path on a graph (which has nothing to do with StarCraft II build orders¹).

END SOLUTION

6 Sorting

1. Answer the following questions with either **True** or **False**. No explanation necessary.

3 pts.

- Binary search on a sorted array is $O(\log n)$ in the worst case.
- Merge Sort requires less memory than Quick Sort.
- Merge Sort is faster than Quick Sort in worst-case scenarios.

SOLUTION:

true

false

true

END SOLUTION

¹It's hard to stress how really broken this question is from a StarCraft II perspective. The DAG is wrong, (the correct one is here http://us.battle.net/sc2/en/game/race/zerg/techtree) and the shortest path isn't meaningful for a build order—you need a topological sort of a subgraph. The question, by design, clearly doesn't benefit from StarCraft II knowledge.

- 2. Counting Sort (Carrano Ch9Ex11): A counting sort is a simple way to sort an array of n positive integers that lie between 0 and m, inclusive. You need m+1 counters. Then, making only one pass through the array, you count the number of times each integer occurs in the array. From the counters, you know how many times each number occurs, and can thus determine the sorted array.
 - (a) Implement the following method that performs counting sort on x, and returns the sorted result by over-writing x, i.e., x will be sorted after calling this method:

8 pts.

```
void countingSort(int[] x, int m) {
SOLUTION:
```

```
int[] countingSort(int[] x, int m) {

   // Count the number of times each integer occurs:
   int n = x.length;
   int[] count = new int[m+1];
   for(int k=0; k<n; k++) count[x[k]] += 1;

   // Generate the sorted array:
   int[] sorted = new int[n];
   int index = 0;
   for(int i=0; i<=m; i++) {
     int mi = count[i];
     for(; index<index+mi; index++) sorted[index] = i;
   }
   return sorted;
}</pre>
```

END SOLUTION

(b) What is the time complexity of this sorting method?

SOLUTION:

O(n+m)

END SOLUTION

7 Concurrency and Threads

1. Answer the following questions with either **True** or **False**. No explanation necessary.

5 pts.

2 pts.

- Every Object (and its subtypes) have an intrinsic lock associated with them.
- synchronized statements are required to be evaluated by multiple threads at the same time.
- A thread invoking an object's synchronized method may also invoke other synchronized methods on the same object.
- Calling Thread.sleep (long millis) puts the main thread to sleep.
- Threads that are not able to execute because other threads are keeping the CPU busy are said to be experiencing "deadlock."

SOLUTION:

true

false

true false false END SOLUTION

2. **Thread-Safety First:** Suppose that you have a large number of int[] arrays for which you would like to compute the sum of all entries. You decide to use thread-parallel computation for speed. Your assistant comes up with the following Thread implementation that accumulates the sum of one int[] into a global variable, sumTotal[0]. Unfortunately he/she can not decide which of the 5 sum methods to use, but hopefully you can help.

```
static class SumTask extends Thread
   static int[] sumTotal = new int[1];
   private int[] v;
   SumTask(int[] v) { this.v = v; }
   public void run() {
      /// WHICH sum?() METHOD TO USE???
   void sum1() {
      for (int x : v) sumTotal[0] = sumTotal[0] + x;
   }
   void sum2() {
      synchronized(sumTotal) {
         for(int x : v) sumTotal[0] = sumTotal[0] + x;
      }
   }
   synchronized void sum3() {
      int sum = 0;
      for (int x : v) sum += x;
      sumTotal[0] = sumTotal[0] + sum;
   }
   void sum4() {
      int sum = 0;
      for (int x : v) sum += x;
      synchronized(this) {
         sumTotal[0] = sumTotal[0] + sum;
      }
   }
   void sum5() {
      int sum = 0;
      for (int x : v) sum += x;
      synchronized(sumTotal) {
         sumTotal[0] = sumTotal[0] + sum;
      }
   }
```

}

Assuming that many SumTask threads are launched in parallel to compute sumTotal:

(a) Which sum? () method should be used to have the best chance of *correctness* and parallel *performance*?

2 pts.

SOLUTION:

sum5()

END SOLUTION

(b) Briefly explain why your choice is best.

4 pts.

SOLUTION:

It allows the thread to independently compute the summation so that multiple threads can run in parallel without synchronization. Only at the end, when its sum is computed, does it synchronize on sumTotal to avoid a memory consistency error when updating. For example, multiple updates to sumTotal could cause one update to be lost, e.g., two threads read the same sumTotal value at the same time, the update and store their values, but only the last thread to store the incremented value will be recorded.

END SOLUTION

3. **Wait/Notify & Synchronization:** Suppose that you decide to start your own internet service provider. You plan to have millions of users, but unfortunately you can only support 5 connections initially. Suppose that you store their Java representations in a List as follows:

```
public class ConnectionPool {
   private List<Connection> connections = createConnections(); // List not threadsafe

private List<Connection> createConnections() {
   List<Connection> conns = new ArrayList<Connection>(5);
   for (int i = 0; i < 5; i++) {
      ... add a Connection to conns
   }
   return conns;
}</pre>
```

You plan to resolve your millions of users' requests for a connection by having them call this method:

```
public Connection getConnection() throws InterruptedException {
   synchronized (connections) {
     while (connections.isEmpty()) {
        connections.wait();
     }
   }
   return connections.remove(0);
}
```

They will return unused connections using this method:

```
public void returnConnection(Connection conn) {
   synchronized (this) {
     connections.notify();
     connections.add(conn);
   }
}
```

Unfortunately both of these latter two methods have problems, and you risk losing millions of customers if you don't fix them:

(a) Something is wrong with getConnection(). Write a better body for this method.

4 pts.

SOLUTION:

```
synchronized (connections) {
  while (connections.isEmpty()) {
    connections.wait();
  }
  return connections.remove(0);
}
```

END SOLUTION

Solution comment (not necessary): connections.remove(0); is outside of the synchronized block, so multiple threads may modify connections. Worse, multiple threads might conceivably call remove(0) when connections only has one entry, or is empty.

(b) Two things are wrong with returnConnection(...). Write a better body for this method.

4 pts.

SOLUTION:

```
synchronized (connections) {
  connections.add(conn);
  connections.notify();
}
```

END SOLUTION

Solution comment (not necessary): It shouldn't synchronize on "this," but rather on "connections" since that may have the threads waiting on it. Furthermore, the notify and add operations are backwards: notify should be called after a connection is made available, not before.

8 Asymptotic Complexity and Induction

1. Answer each of the following questions by stating the computational complexity in Big Oh notation. No explanation necessary. Report the tightest bound you can, e.g., do not report $O(n^2)$ when O(n) will do.

8 pts.

• (Carrano Ch4Q8): The following algorithm discovers whether an array contains duplicates within its first n elements. What is the worst-case cost of this algorithm?

```
boolean hasDuplicates(int[] array, int n)
    for(int index=0; index<=n-2; index++) {</pre>
      for(int rest=index+1; rest<=n-1; rest++) {</pre>
        if(array[index] == array[rest])
        return true;
      }
    }
    return false
  }
SOLUTION:
O(n^2)
END SOLUTION
```

• (Carrano Ch4Ex10) What is the cost of the following computation?

```
int sum = 0;
  for(int counter=n; counter>0; counter=counter-2)
    sum = sum + counter;
SOLUTION:
O(n)
```

END SOLUTION

• (Carrano Ch4Ex11) What is the cost of the following computation?

```
int sum = 0;
for(int counter=0; counter<n; counter=counter*2)</pre>
  sum = sum + counter;
```

SOLUTION:

It would seem to be $O(\log n)$, but it is actually an infinite loop. Stating so, or stating $O(\infty)$ gets full points.

END SOLUTION

• What is the cost of the following computation?

```
int sum = 0;
for(int i=0; i<n; i+=100) {
  for(int j=0; j<1000*n; j++) {
    for (int k=0; k<j/1000; k++) {
      for(int l=0; l<1000000; l++) {
        sum += i+j+k-l;
      }
    }
  }
}
```

SOLUTION:

 $O(n^3)$

END SOLUTION

2. **Mathematical Induction:** Assume that you have a recursive algorithm that has worst-case time complexity bounded by the following recurrence relation.

$$T(1) = 2$$

 $T(n) = T(n-1) + 3(n-1)^2$

In the following you will use weak mathematical induction to prove that the algorithm is $O(n^3)$.

• State and prove the Base Case.

3 pts.

SOLUTION:

NOTE: We wish to establish that $T(n) = O(n^3)$ by finding a witness pair (c, N) such that $T(n) \le cn^3$, for all $n \ge N$. We will establish that c = 2 and N = 1 is such a pair.

The base (n = 1) case is simply

$$T(1) = 2 \le cn^3 = (2)(1)^3 = 2$$

for c=2, and N=1. (Note that we've looked ahead to see that this (c,N) pair will work.) END SOLUTION

• State the Inductive Hypothesis.

4 pts.

SOLUTION:

Assume the n^{th} case:

$$T(n) = T(n-1) + 3(n-1)^2 \le cn^3$$

for all $n \ge N = 1$ and c = 2.

END SOLUTION

• Perform the Induction Step. Use the back of this page if you need more room. (Simplifying hint: ((n+1)-1)=n)

6 pts.

SOLUTION:

We need to show that the $(n+1)^{th}$ case is implied by the n^{th} case, and therefore conclude the proof by simple induction.

The $(n+1)^{th}$ case we want to show is that

$$T(n+1) = T(n) + 3n^2 \le c(n+1)^3$$

for our (c, N), with $n \geq N$. Using the identify for T(n), and the bound for the assumed n^{th} case,

$$T(n+1) = T(n) + 3n^{2}$$

$$= (T(n-1) + 3(n-1)^{2}) + 3n^{2}$$

$$\leq cn^{3} + 3n^{2}$$

$$= c(n+1)^{3} + \{cn^{3} - c(n+1)3 + 3n^{2}\}$$

$$= c(n+1)^{3} + \{-3(c-1)n^{2} - 3cn - c\}$$

which satisfies the $(n+1)^{th}$ case inequality provided that the curly-brace quantity is not positive for our (c, N). Fortunately this is the case, since

$$\left\{ -3(c-1)n^2 - 3cn - c \right\} \le 0$$

for c=2 and $n\geq N=1$.

It follows by the principle of simple induction that $T(n) = O(n^3)$.

END SOLUTION
