text javabear to 22333

On the left is a *buggy* `med3()` definition. Which JUnit assertion will detect the bug?

```
1  /** Returns median of `a`, `b`, `c`. */
2  static int med3(int a, int b, int c) {
3      if (a >= b) {
4          return Math.max(b, c);
5      } else if (a >= c) { // a < b
6          return a;
7      } else { // a is smallest
8          return Math.min(b, c);
9      }
10 }
```

*a can be median even if  $a \geq b$*

`assertEquals(2, med3(1, 2, 3));` (A)

`assertEquals(2, med3(2, 3, 1));` (B)

`assertEquals(2, med3(2, 1, 3));` (C)

`assertEquals(2, med3(3, 1, 2));` (D)

# Lecture 4: Loop Invariants

CS 2110

September 3, 2026

# Today's Learning Outcomes

- 18. Identify the loop invariant of an iterative method involving an array and visualize it using an array diagram.
- 19. Use an array diagram to develop an iterative method that maintains the visualized invariant.
- 20. Write precise specifications for methods involving arrays that use range notation.

# Loop Anatomy

```
int sum = 0;  
for (int i = 0; i < a.length; i++) {  
    sum += a[i];  
}
```

Loop body

Increment: loop variable(s)

Initialization:  
declare + initialize  
loop variable(s)

Loop guard:  
boolean expression  
true  $\Rightarrow$  run loop body  
false  $\Rightarrow$  "fall through"  
loop

# while Loops

Built from all the same components as for loops.

Every for loop can be transformed into a while loop.

```
int sum = 0;  
for (int i = 0; i < a.length; i++) {  
    sum += a[i];  
}
```

```
int sum = 0;  
int i = 0;  
while (i < a.length) {  
    sum += a[i];  
    i++;  
}
```

We'll focus on while loops today, but everything also applies to for loops.

# Range Notation

A **range** of an array is a contiguous subset of its entries.

$$a[2..5] = a(1..6) = a(2..6)$$

include endpoints

exclude endpoints

Special cases:

from start

$$\begin{cases} a[\text{red}..i] = a[0..i] \\ a(0..i) = a(\text{red}..i) \end{cases}$$

from end

$$\begin{cases} a[i..\text{red}] = a[i..a.length-1] \\ \vdots \end{cases}$$

$a[i..j]$  empty when  $i > j$

# Range Properties and Array Diagrams

We use **array diagrams** as a tool to visualize properties of array ranges.

# Writing "Loopy" Code

```
1  /** Returns # of occurrences of `key` in array `a`. */  
2  static int frequencyOf(int key, int[] a) { ... }
```

Pre:      a:            a.length

when we enter the  
method/loop, we don't  
know anything about a's  
contents

\*no pre-conditions

# Writing "Loopy" Code

```
1  /** Returns # of occurrences of `key` in array `a`. */  
2  static int frequencyOf(int key, int[] a) { ... }
```

**Pre:** a:  0 a.length

**Post:** a:  0 a.length

↖ need to introduce local  
variable where we'll  
keep track of count

# Writing "Loopy" Code

```
1  /** Returns # of occurrences of `key` in array `a`. */  
2  static int frequencyOf(int key, int[] a) { ... }
```

**Pre:** a: 

**Post:** a: 

**Inv:** a: 

strategy:  
count while  
scanning left  
to right

# (Loop) Invariants

An **invariant** is an assertion about code that is true at multiple predetermined points of its execution.

A loop invariant describes relationship between loop + other local vars that is true every time loop guard is evaluated.

Loop Inv : count = # of occurrences of key in a[..i)

Once we have a loop invariant diagram, writing its loop becomes mechanical.

# Developing a Loop: Initialization

```
1  /** Returns # of occurrences of `key` in array `a`. */
2  static int frequencyOf(int key, int[] a) {
3      int i = 0;    // i = next index of 'a' to check
4      int count = 0;
5
6      /* Loop Inv: `count` = # of occurrences of `key` in `a[..i)` */
7      while (...) { ... }
8  }
```

(start by checking  $a[0]$ )

$a[..0)$  is empty

Initialize local variables to *truthify* the loop invariant when we enter the loop.

**Pre:**  $a:$  

**Inv:**  $a:$  

# Poll Everywhere

PollEv.com/javabear

text `javabear` to 22333

Which of these is true *immediately after* we fall through the loop body?

loop invariant is **true**

loop guard is **true**

(A)

loop invariant is **true**

loop guard is **false**

loop invariant is **false**

loop guard is **true**

(C)

loop invariant is **false**

loop guard is **false**

(D)

# Developing a Loop: Guard + Post-condition

```
1  /** Returns # of occurrences of `key` in array `a`. */
2  static int frequencyOf(int key, int[] a) {
3      int i = 0; // next index of `a` to check
4      int count = 0;
5      /* Loop Inv: `count` = # of occurrences of `key` in `a[..i)` */
6      while (i < a.length) { ... } // done when i == a.length
7      return count;
8  }
```

$a[..a.length)$  is all of  $a$

negate\*  
continue looping while  $i < a.length$

Guard the loop on a condition that *falsifies* once the loop is done with its work.

Use loop invariant to meet method post-condition.

# Developing a Loop: Body

In each iteration:

- Progress toward the loop's goal
- Restore the loop invariant

```
1  /** Returns # of occurrences of `key` in array `a`. */
2  static int frequencyOf(int key, int[] a) {
3      int i = 0; int count = 0;
4      /* Loop Inv: `count` = # of occurrences of `key` in `a[..i)` */
5      while (i < a.length) {
6          if (a[i] == key) {
7              count++;
8          }
9          i++;
10     }
11     return count;
12 }
```

increase count if  
== key

then, safe to slide  
boundary right to  
restore invariant

## Example 2: argmin()

```
1  /** Returns an *index* of the minimum element in `a`.
2   * Requires that `a.length > 0`. */
3  static int argmin(double[] a) { ... }
```

`argmin(new double[]{1.0, 3.5, 4.2, 0.7, 6.3, 2.8}) = 3`

0      1      2      3

What do we need to keep track of to compute the `argmin()`?

- which entries we've checked (i)
- the smallest element we've seen (min)
- where this smallest element is (loc)

# argmin() Invariant Diagram

similar strategy sweeping left  $\rightarrow$  right will work

state fact that min  
is smallest value  
we've seen as a  
range property

$a[loc] = min$

this isn't a range property,  
so we'll write it below the  
diagram

# Exercise

Use the array diagram we developed to complete the definition of `argmin()`.

```
1  /** Returns an *index* of the minimum element in `a`.
2   * Requires that `a.length > 0`. */
3  static int argmin(double[] a) { ... }
```

# argmin() Pre and Post Diagrams

# Coding Demo: `argmin()`

# Example 3: paritySplit()

```
1  /** Rearranges `a` so that all even elements appear before
2   *   all odd elements. Returns the index of the first odd
3   *   element, or `a.length` if all elements are even. */
4  static int paritySplit(int[] a) { ... }
```

|     |     |     |     |     |     |     |
|-----|-----|-----|-----|-----|-----|-----|
| 2   | 1   | 3   | 6   | 4   | 5   | 0   |
| [0] | [1] | [2] | [3] | [4] | [5] | [6] |

→

|     |     |     |     |     |     |     |
|-----|-----|-----|-----|-----|-----|-----|
| 2   | 6   | 4   | 0   | 1   | 3   | 5   |
| [0] | [1] | [2] | [3] | [4] | [5] | [6] |

or

↘

|     |     |     |     |     |     |     |
|-----|-----|-----|-----|-----|-----|-----|
| 0   | 2   | 4   | 6   | 5   | 1   | 3   |
| [0] | [1] | [2] | [3] | [4] | [5] | [6] |

return 4

\* look at lecture  
code to see  
how we test this!

(under specified)  
⋮

# paritySplit() Array Diagrams

\* We can put  $i, j$  on the other sides of the boundaries, giving another (correct) definition. See Lecture Exercise 4.7.

# Coding Demo: `paritySplit()`

# paritySplit() Loop Body

Inspect  $a[i]$  and consider two cases:

1.  $a[i]$  is even

2.  $a[i]$  is odd

# Review: Steps for Developing Loops

1. Think about loop progress to sketch its invariant.
2. Identify local variables: one per boundary, perhaps others for properties.
3. Use the “Inv” diagram to write the loop invariant comment.
4. Slide the “Inv” boundaries to their "Pre" positions
  - Use overlaps to initialize the loop variables.
  - Use the loop invariant to initialize other local variables.
5. Slide the “Inv” boundaries to their "Post" positions
  - Use overlaps to determine the loop guard.
  - Use the loop invariant to satisfy the method post-conditions
6. Develop the loop body so that it:
  - Makes progress toward the post-condition.
  - Re-establishes the loop invariant.
