

# Event-Driven Programming

Lecture 21

CS2112 – Fall 2024

# JavaFX GUI

<http://docs.oracle.com/javase/8/javase-clienttechnologies.htm>

- Output (statics): what's drawn on the screen
  - Nodes
    - Buttons, labels, lists, sliders, canvas, ...
  - Parent nodes: contain other nodes, control layout
    - Pane, HBox, VBox, GridPane, StackPane, Group, ...
  - Helper classes
    - Graphics, Color, Font, FontMetrics, Dimension
- Input (dynamics): handling events
  - User-generated events
    - Button-press, mouse-click, key-press, ...
    - EventHandlers: methods that respond to events
  - Properties
    - Listeners
    - Animation

# UI Builder Tool

<https://gluonhq.com/products/scene-builder/>

- The JavaFX Scene Builder makes XML representation of UI node layouts

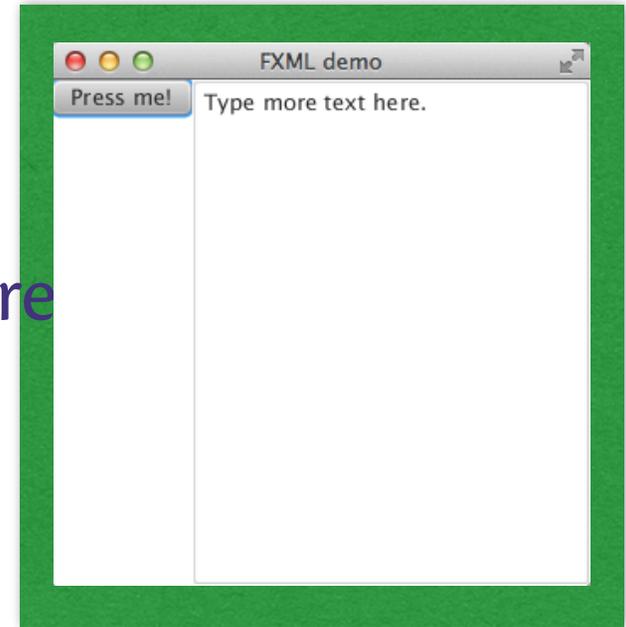

- Example: simple.fxml

```
<?xml version="1.0" encoding="UTF-8"?>
```

```
...
```

```
<AnchorPane id="AnchorPane" prefHeight="299.0" prefWidth="319.0"
xmlns:fx="http://javafx.com/fxml/1" xmlns="http://javafx.com/javafx/2.2"
  <children>
    <HBox layoutX="0.0" layoutY="0.0" prefHeight="299.0"
prefWidth="333.0">
      <children>
        <Button id="pressme" mnemonicParsing="false" text="Press me!" />
        <TextArea id="typeme" prefHeight="299.0" prefWidth="236.0"
text="Type more text here." wrapText="true" />
      </children>
    </HBox>
  </children>
</AnchorPane>
```

- Read XML into UI nodes with  
FXMLLoader.load(url)

# Example

```
class PrintIt implements EventHandler<ActionEvent> {
    @Override
    public void handle(ActionEvent ae) {
        System.out.println("Button was clicked");
    }
}

public class Main extends Application {
    public void start(Stage stage) throws Exception {
        try {
            URL r = getClass().getResource("simple.fxml");
            if (r == null) ...; // error
            Scene scene = new Scene(FXMLLoader.load(r));
            stage.setScene(scene);
            stage.sizeToScene();
            Button b = (Button) scene.lookup("#pressme");
            b.setOnAction(new PrintIt());
            stage.show();
        } catch ... // error
    }
}
```

*creating the node hierarchy* {

# Events

<http://docs.oracle.com/javase/8/javafx/events-tutorial/events.htm#JFXED117>

- GUI code responds to (and creates) events
  - mouse button, keyboard pressed, mouse motion, window exposed,...
  - All subclasses of `javafx.ui.Event`
- Some nodes already handle events on their own, generate new events, e.g.:
  - Buttons: mouse press, release → 'button clicked'
  - Scrollbar: mouse clicks, motion → scrollbar value
  - Multiple press/release events → 'double-click'
- Application defines how to handle both 'raw' and synthesized events, can generate its own events

# Event Handlers

- An `EventHandler<T>` is an object that handles events of type `T`:

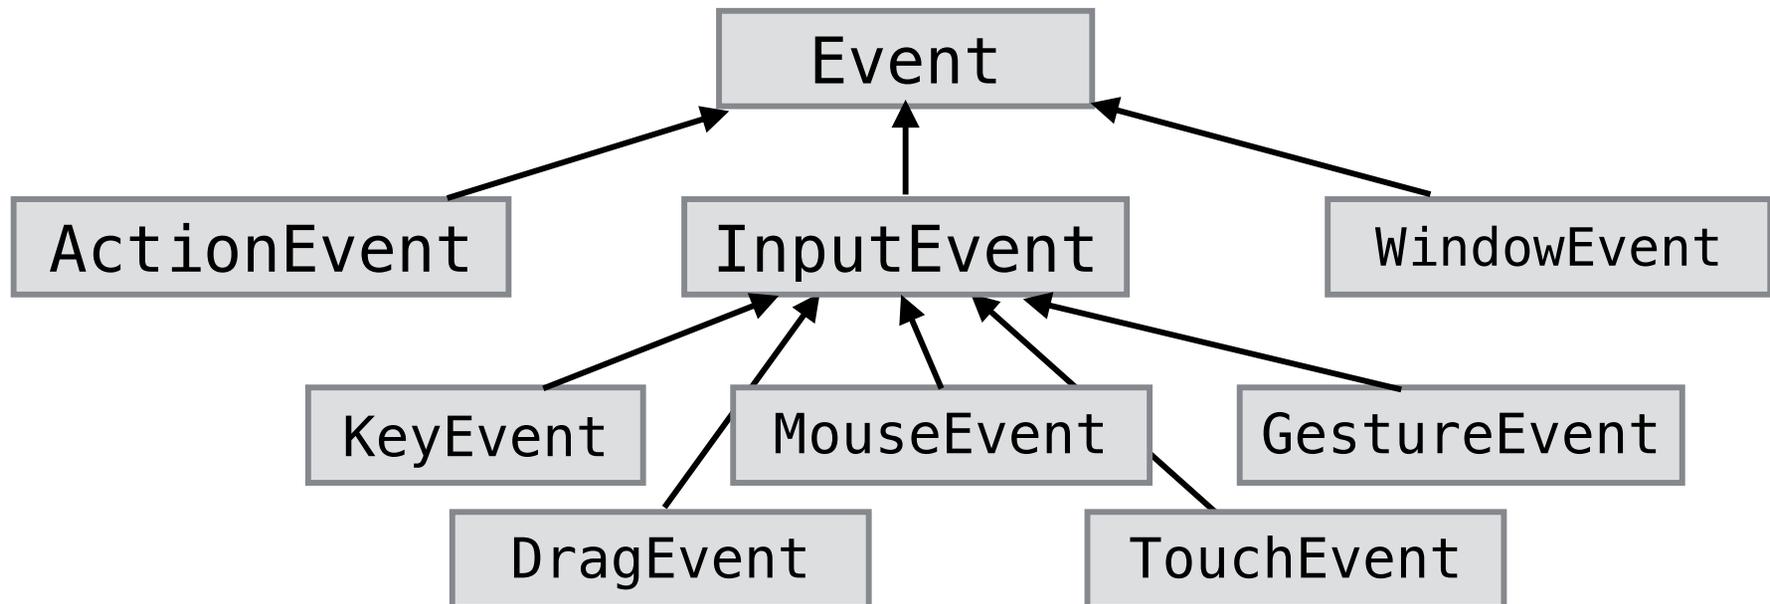

```
interface EventHandler<T> {  
    void handle(T event);  
}
```

- Event handlers can be registered with nodes that generate events:

```
Button b = new Button("press me");  
b.setOnAction(myButtonHandler);  
Scrollbar s = new Scrollbar();  
s.setOnScroll(myScrollEventHandler);
```

*Note:  
there can  
be only  
one.*

# Event Types

- Different kinds of events represented by different event classes
- E.g., MouseEvent reports mouse position

# Delegation Model

- Timeline for an event
  - User (or program) does something to a component, event is generated
  - Event is passed down **event dispatch chain** to find handlers for event
    - Event dispatch chain determined by the **event target** the event is sent to (e.g., the window = Stage)
    - Event dispatch chain usually corresponds to chain of nodes in layout tree from root to leaf—can be overridden, but usually not necessary
  - Each event handler uses event to update application state appropriately
    - handler can modify, consume event (so not seen by rest of chain), generate new events

# Accessing State from Handler

```
class PrintIt implements EventHandler<ActionEvent> {
    Main main;
    PrintIt(Main m) { main = m; }
    @Override
    public void handle(ActionEvent ae) {
        System.out.println(main.message);
    }
}

public class Main extends Application {
    String message = "Button was clicked";
    public void start(Stage stage) throws Exception {
        ...
        Button b = (Button) scene.lookup("#pressme");
        b.setOnAction(new PrintIt(this));
        ...
    }
}
```

# Event Handler as Main

```
public class Main extends Application
    implements EventHandler<ActionEvent> {
    String message = "Button was clicked";
    public void start(Stage stage) throws Exception {
        ...
        Button b = (Button) scene.lookup("#pressme");
        b.setOnAction(this);
        ...
    }
    public void handle(ActionEvent ae) {
        System.out.println(message);
    }
}
```

# Event Handler as Inner Class

```
public class Main extends Application {
    String message = "Button was clicked";
    public void start(Stage stage) throws Exception {
        ...
        Button b = (Button) scene.lookup("#pressme");
        b.setOnAction(new PrintIt());
        ...
    }
    class PrintIt implements EventHandler<ActionEvent> {
        public void handle(ActionEvent ae) {
            System.out.println(message);
        }
    }
}
```

# ...as Anonymous Inner Class

```
public class Main extends Application {
    String message = "Button was clicked";
    public void start(Stage stage) throws Exception {
        ...
        Button b = (Button) scene.lookup("#pressme");
        b.setOnAction(new EventHandler<ActionEvent> () {
            public void handle(ActionEvent ae) {
                System.out.println(message);
            }
        });
    }
}
```

# ...with lambda expression

```
public class Main extends Application {  
    String message = "Button was clicked";  
    public void start(Stage stage) throws Exception {  
        ...  
        Button b = (Button) scene.lookup("#pressme");  
        b.setOnAction(e -> System.out.println(message));  
    }  
}
```

# Properties

<http://docs.oracle.com/javafx/2/binding/jfxpub-binding.htm>

- Another way to access dynamic behavior in JavaFX: **properties** of nodes
- Node accessors correspond to property objects:

<code>boolean isDisabled()</code>	<code>BooleanProperty disabledProperty()</code>
<code>double getWidth(), getHeight()</code>	<code>ReadOnlyDoubleProperty widthProperty(), heightProperty()</code>
<code>double getLayoutX(), getLayoutY()</code>	<code>DoubleProperty layoutXProperty(), layoutYProperty()</code>
<code>Paint getTextFill()</code>	<code>ObjectProperty&lt;Paint&gt; textFillProperty()</code>
<code>String getText()</code>	<code>StringProperty getTextProperty()</code>

# Listening to Properties

- Program actions can be triggered by changes to properties, by attaching **listeners**

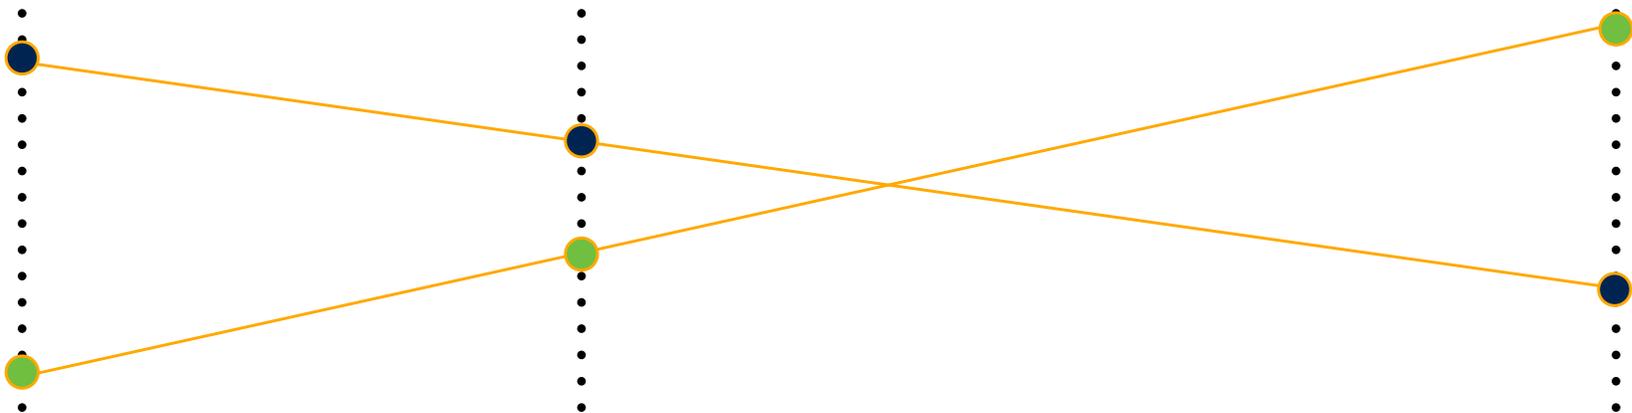

```
TextArea t = ...;
t.textProperty().addListener(new ChangeListener<String>() {
    void changed(ObservableValue<? extends String> obs,
                String before, String after) {
        System.out.format(
            "Changed from \"%s\" to \"%s\"\n",
            before, after);
    }
});
```

- Any number of listeners can be attached
- Design pattern: Observer

# Animations

<http://docs.oracle.com/javafx/2/animations/jfxpub-animations.htm>

- Properties can be controlled by animations
- Animation is defined by a sequence of **key frames**
- Each key frame has a time instant and defines the values of some set of properties
- JavaFX interpolates property values smoothly between key frames

# Creating an Animation

- “Over the next 0.5 seconds, increase the Y position of the button by 10 pixels”

```
Timeline t1 = new Timeline();  
t1.getKeyFrames().add(new KeyFrame(  
    Duration.millis(500), "done",  
    new KeyValue(b.layoutYProperty(),  
                b.getLayoutY() + 10.0)));  
t1.play();
```

Property to interpolate

Current Y position

# Binding Properties

<http://docs.oracle.com/javafx/2/binding/jfxpub-binding.htm>

- Properties can be bound to **computations** rather than to **values**

```
Button b1 = new Button();  
Button b2 = new Button();  
DoubleProperty p = b2.getLayoutY();  
p.bind(b1.layoutYProperty().add(  
    new SimpleDoubleProperty(10.0)));
```

- Effect: b2's Y position is recomputed and updated automatically as b1's Y position changes
