Variables	Visibility	Lifetime	Location
Function-Local i, m, count, A, argc, argv	within function	function invocation	stack
Global n	whole program	program execution	.data
Dynamic *A	?	between malloc and free	heap

```
int n = 100;
int main (int argc, char* argv[ ]) {
        int i, m = n, count = 0, *A = malloc(4 * m);
        for (i = 1; i <= m; i++) { count += i; A[i] = count; }
        printf ("Sum 1 to %d is %d\n", n, count);
}
```

Variables	Visibility	Lifetime	Location
Function-Local (i, m, count, A, argc, argv)	within function	function invocation	stack
Global (n)	whole program	program execution	.data
Dynamic (*A)	?	between malloc and free	heap

C Pointers can be trouble

```
int *trouble()
{ int a; …; return &a; }
char *evil()
{ char s[20]; gets(s); return s;
int *bad()
{ s = malloc(20); … free(s); … return s; }
```

"address of" something on stack!
also on stack! Both invalid after return!
points to free space in heap

(Can't do this in Java, C#, …)

Variables	Visibility	Lifetime	Location

Executing in Memory
Linker
executable
Compiler
C
Assembler
assembly
Loader
machine code
process

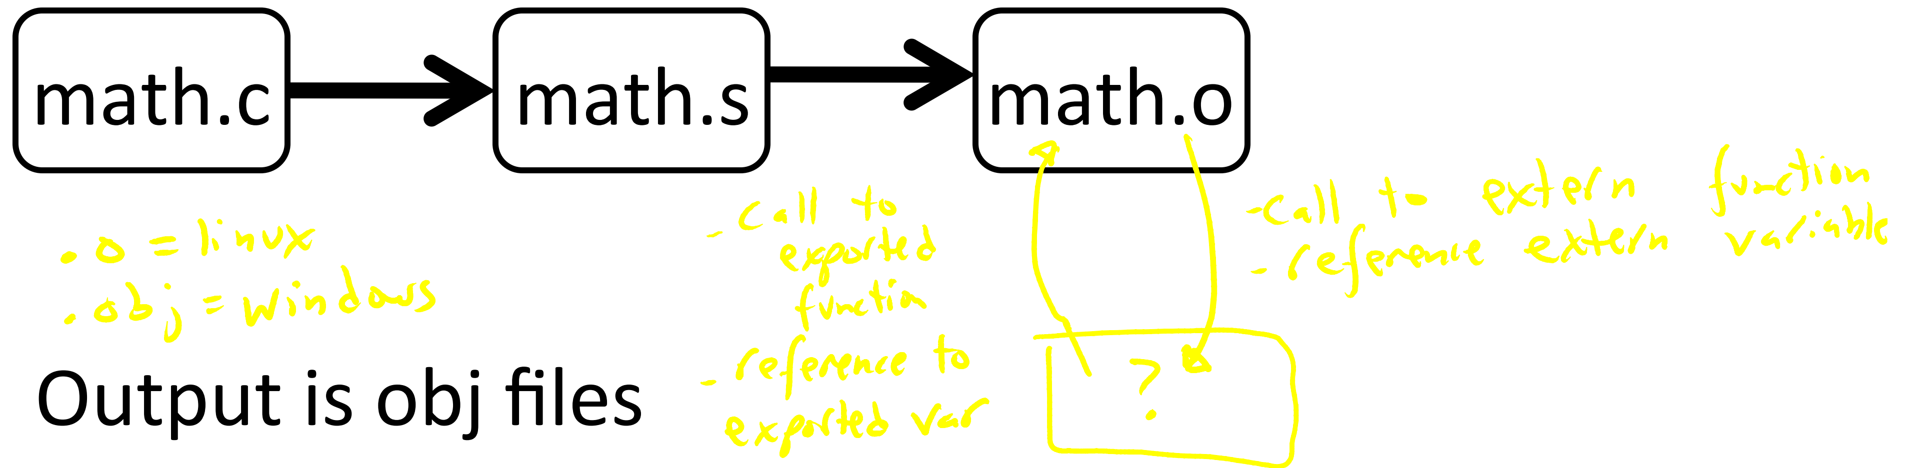
Compiler output is assembly files

Assembler output is obj files

Linker joins object files into one executable

Loader brings it into memory and starts execution

Compilers and Assemblers



Output is obj files

- Binary machine code, but not executable
- May refer to external symbols
- Each object file has illusion of its own address space
  - Addresses will need to be fixed later

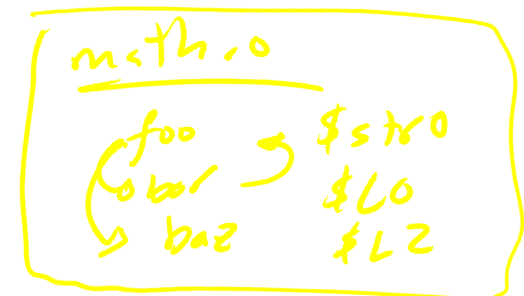
- code starts at 0x0
- data starts at 0x0

Global labels: Externally visible "exported" symbols

- Can be referenced from other object files
- Exported functions, global variables

Local labels: Internal visible only symbols

- Only used within this object file
- static functions, static variables, loop labels, …



Object File

Header
- Size and position of pieces of file

Text Segment
- instructions

Data Segment
- static data (local/global vars, strings, constants)

Debugging Information
- line number   code address map, etc.

Symbol Table
- External (exported) references
- Unresolved (imported) references

math.c

```
int pi = 3;
int e = 2;
static int randomval = 7;

extern char *username;
extern int printf(char *str, ...);

int square(int x) { ... }
static int is_prime(int x) { ... }
int pick_prime() { ... }
int pick_random() {
    return randomval;
}
```

```
gcc -S ... math.c
gcc -c ... math.s
objdump --disassemble math.o
objdump --syms math.o
```

Objdump disassembly

```
csug01 ~$ mipsel-linux-objdump --disassemble math.o
math.o:     file format elf32-tradlittlemips

calc.exe
linker
Executing in Memory

Linker combines object files into an executable file

- Relocate each object's text and data segments
- Resolve as-yet-unresolved symbols
- Record top-level entry point in executable file

End result: a program on disk, ready to execute

main.o

```

Object File

Header

- location of main entry point (if any)

Text Segment

- instructions

Data Segment

- static data (local/global vars, strings, constants)

Relocation Information

- Instructions and data that depend on actual addresses
- Linker patches these bits after relocating segments

Symbol Table

- Exported and imported references

Debugging Information

Unix

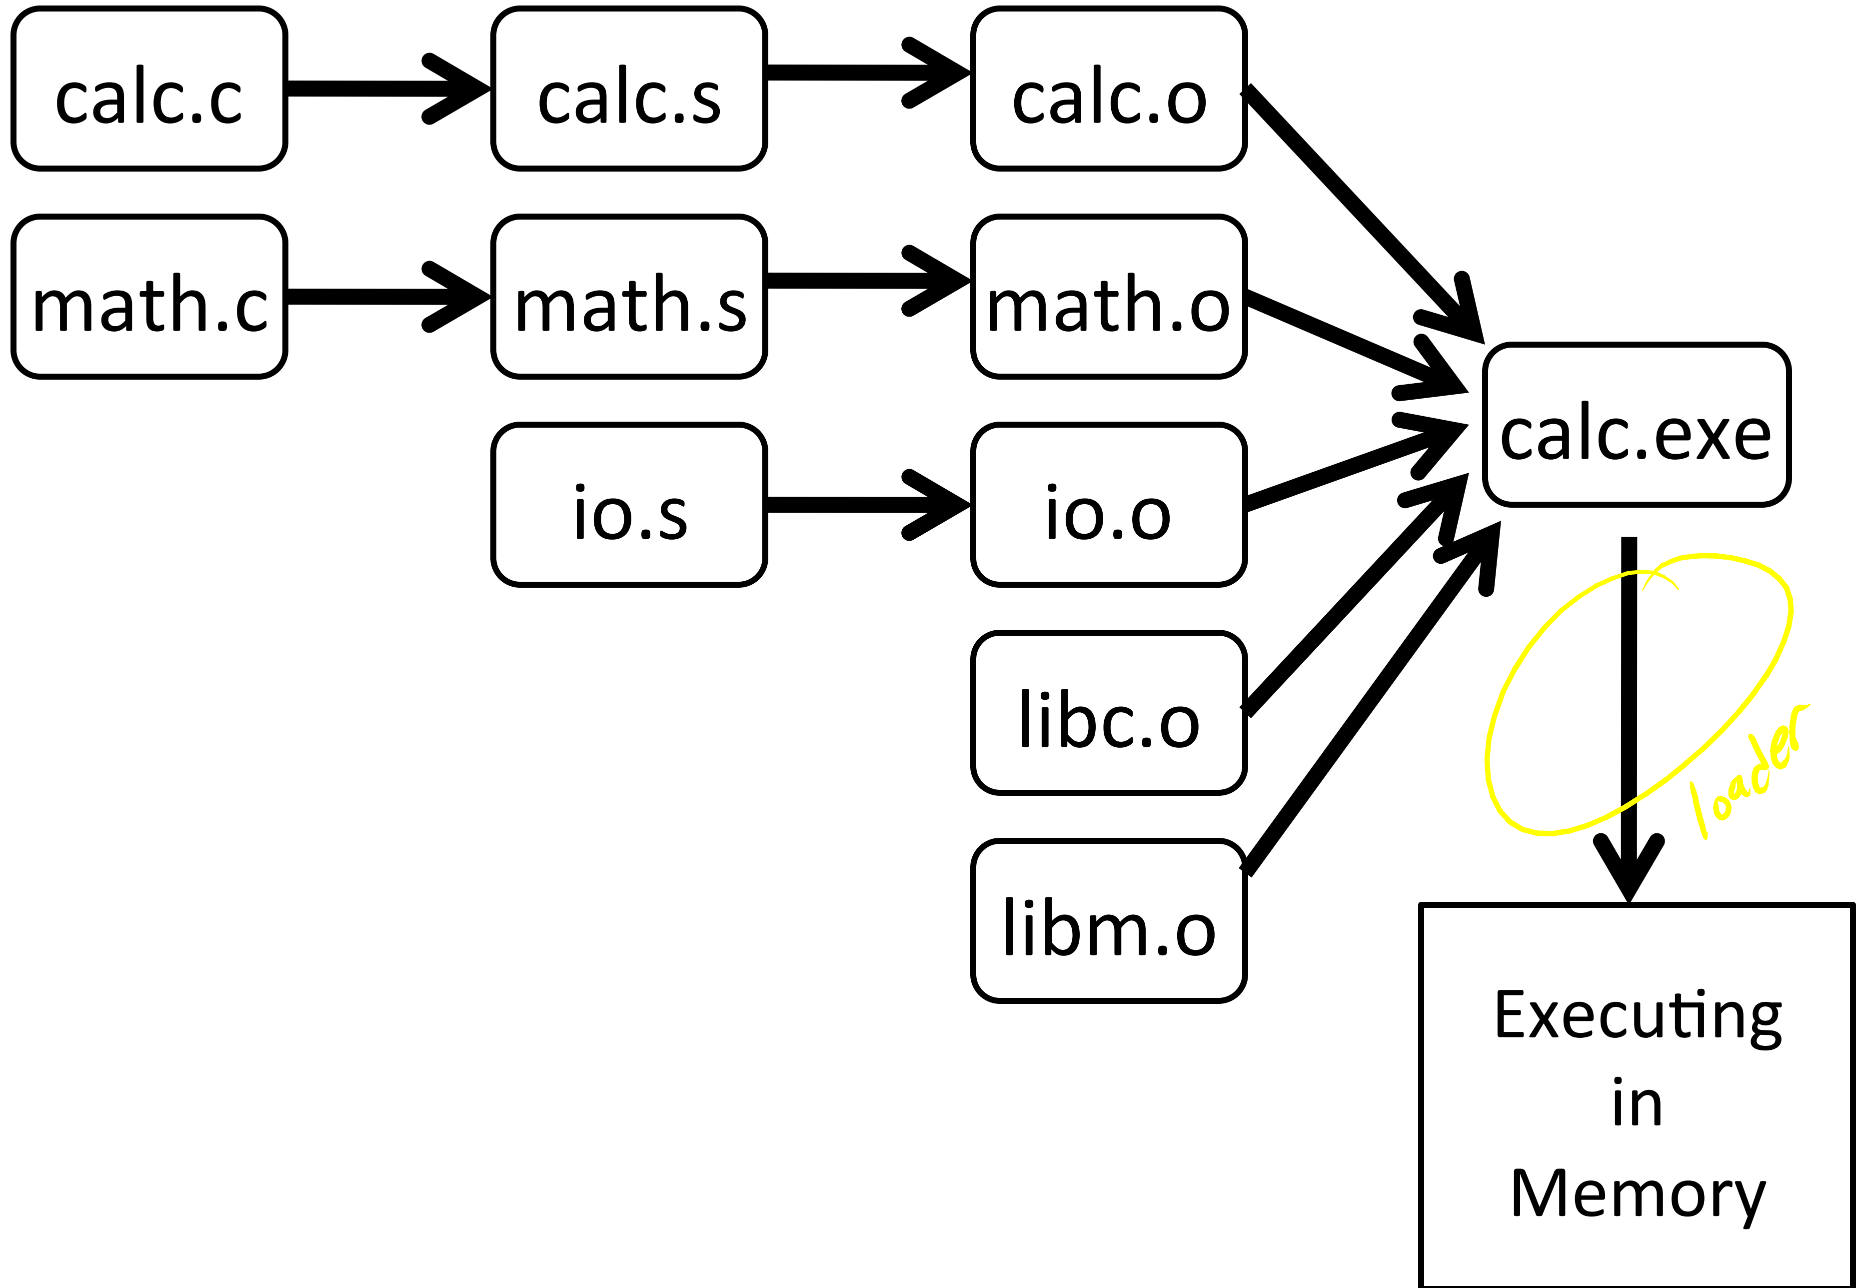
- a.out — older
- COFF: Common Object File Format
- ELF: Executable and Linking Format
- …

Windows

- PE: Portable Executable

All support both executable and object files

Loaders and Libraries



calc.c
calc.s
calc.o
math.c
math.s
math.o
io.s
io.o
libc.o
libm.o
calc.exe
loader
Executing in Memory

Loader reads executable from disk into memory

- Initializes registers, stack, arguments to first function
- Jumps to entry-point

Part of the Operating System (OS)

Static Library: Collection of object files (think: like a zip archive)

.a = linux
.lib = windows

Q: But every program contains entire library!

A: Linker picks only object files needed to resolve undefined references at link time

e.g. libc.a contains many objects:

- printf.o, fprintf.o, vprintf.o, sprintf.o, snprintf.o, …
- read.o, write.o, open.o, close.o, mkdir.o, readdir.o, …
- rand.o, exit.o, sleep.o, time.o, ….

Q: But every program still contains part of library!

A: shared libraries

- executable files all point to single *shared library* on disk
- final linking (and relocations) done by the loader

Optimizations:

- Library compiled at fixed non-zero address

- Jump table in each program instead of relocations
- Can even patch jumps on-the-fly

Direct call:

```
00400010 <main>:
  ...
  jal 0x00400330
  ...
  jal 0x00400620
  ...
  jal 0x00400330
  ...
00400330 <printf>:
  ...
00400620 <gets>:
  ...
```

Drawbacks:

Linker or loader must edit every use of a symbol (call site, global var use, ...)

Idea:

Put all symbols in a single "global offset table"

Code does lookup as needed

```
00400010 <main>:
  ...
  jal 0x00400330
  ...
  jal 0x00400620
  ...
  jal 0x00400330
  ...
00400330 <printf>:
  ...
00400620 <gets>:
  ...
```

GOT: global offset table

Indirect call:

```
00400010 <main>:
  ...
  lw t9, ? # printf
  jalr t9
  ...
  lw t9, ? # gets
  jalr t9
  ...
00400330 <printf>:
  ...
00400620 <gets>:
  ...
```

```
# data segment
  ...
  ...
# global offset table
# to be loaded
# at -32712(gp)
.got
.word 00400010 # main
.word 00400330 # printf
.word 00400620 # gets
  ...
```

Indirect call with on-demand dynamic linking:

```
00400010 <main>:
   ...
   # load address of prints
   # from .got[1]
   lw t9, -32708(gp)
   # also load the index 1
   li t8, 1
   # now call it
   jalr t9
   ...
.got
   .word 00400888 # open
   .word 00400888 # prints
   .word 00400888 # gets
   .word 00400888 # foo
```

```
   ...
00400888 <dlresolve>:
   # t9 = 0x400888
   # t8 = index of func that
   #    needs to be loaded

   # load that func
   ... # t7 = loadfromdisk(t8)

   # save func's address so
   # so next call goes direct
   ... # got[t8] = t7

   # also jump to func
   jr t7
   # it will return directly
   # to main, not here
```

Executing
in
Memory

Windows: dynamically loaded library (DLL)

- PE format

Unix: dynamic shared object (DSO)

- ELF format

Unix also supports Position Independent Code (PIC)

- Program determines its current address whenever needed (no absolute jumps!)
- Local data: access via offset from current PC, etc.
- External data: indirection through Global Offset Table (GOT)
- … which in turn is accessed via offset from current PC

Static linking

Dynamic linking
