### Introduction to Compilers Tim Teitelbaum

#### Lecture 32: More Instruction Selection 20 Apr 05

CS 412/413 Spring 2005

Introduction to Compilers

1

## Instruction Selection

1. Translate low-level IR code into DAG representation
2. Then find a good tiling of the DAG
  - disjoint set of tiles that cover the DAG
  - Maximal munch algorithm
  - Dynamic programming algorithm

CS 412/413 Spring 2005

Introduction to Compilers

2

## DAG Tiling

- **Goal:** find a good covering of DAG with tiles
- **Problem:** need to know what variables are in registers
- **Assume abstract assembly:**
  - Machine with infinite number of registers
  - Temporary/local variables stored in registers
  - Parameters/heap variables: use memory accesses

CS 412/413 Spring 2005

Introduction to Compilers

3

## Problems

- **Classes of registers**
  - Registers may have specific purposes
  - Example: Pentium multiply instruction
    - multiply register eax by contents of another register
    - store result in eax (low 32 bits) and edx (high 32 bits)
    - need extra instructions to move values into eax
- **Two-address machine instructions**
  - Three-address low-level code
  - Need multiple machine instructions for a single tile
- **CISC versus RISC**
  - Complex instruction sets => many possible tiles and tilings
  - Example: multiple addressing modes (CISC) versus load/store architectures (RISC)

CS 412/413 Spring 2005

Introduction to Compilers

4

## Pentium ISA

- **Pentium:** two-address CISC architecture
- **Multiple addressing modes:** source operands may be
  - Immediate value: imm
  - Register: reg
  - Indirect address: [reg], [imm], [reg+imm],
  - Indexed address: [reg+reg'], [reg+imm\*reg'], [reg+imm\*reg'+imm']
- Destination operands = same, except immediate values

CS 412/413 Spring 2005

Introduction to Compilers

5

## Example Tiling

- Consider:  $t = t + i$   
t = temporary variable  
i = parameter
- Need new temporary registers between tiles (unless operand node is labeled with temporary)
- Resulting code:

```
mov %ebp, t0
sub $20, t0
mov 0(t0), t1
add t1, t
```

CS 412/413 Spring 2005

Introduction to Compilers

6

## Tiles

mov t1, t2  
add \$1, t2

- Tiles capture compiler's understanding of instruction set
- Each tile: sequence of machine instructions that match a subgraph of the DAG
- May need additional move instructions
- Tiling = cover the DAG with tiles

CS 412/413 Spring 2005

Introduction to Compilers

7

## Some Tiles

mov t2, t1

mov \$10, 0(t1,t2)

mov t2, t3  
add t1, t3

mov t1, %eax  
mul t2  
mov %eax, t3

CS 412/413 Spring 2005

Introduction to Compilers

8

## Conditional Branches

- How to tile a conditional jump?
- Fold comparison into tile

test t1,t1  
jnz L

cmp t1,t2  
je L

CS 412/413 Spring 2005

Introduction to Compilers

9

## Maximal Munch Algorithm

- Maximal Munch = find largest tiles (greedy algorithm)
- Start from top of tree
- Find largest tile that matches top node
- Tile remaining subtrees recursively

CS 412/413 Spring 2005

Introduction to Compilers

10

## DAG Representation

- DAG: a node may have multiple parents
- Algorithm: same, but a node with multiple parents occurs inside a tile only if all its parents are in the tile

CS 412/413 Spring 2005

Introduction to Compilers

11

## Example

x = x + 1;

CS 412/413 Spring 2005

Introduction to Compilers

12

## Example

$x = x + 1;$

```

mov 8(%ebp), t1
mov t1, t2
add $1, t2
mov t2, 8(%ebp)
    
```

CS 412/413 Spring 2005

Introduction to Compilers

13

## Alternate (CISC) Tiling

$x = x + 1;$

```
add $1, 8(%ebp)
```

CS 412/413 Spring 2005

Introduction to Compilers

14

## ADD Expression Tiles

```
mov t2, t1
add r/m32, t1
```

```
mov t2, t1
add imm32, t1
```

CS 412/413 Spring 2005

Introduction to Compilers

15

## ADD Statement Tiles

Intel Architecture

```

add imm32, %eax
add imm32, r/m32
add imm8, r/m32
add r32, r/m32
add r/m32, r32
    
```

CS 412/413 Spring 2005

Introduction to Compilers

16

## Designing Tiles

- Only add tiles that are useful to compiler
- Many instructions will be too hard to use effectively or will offer no advantage
- Need tiles for all single-node trees to guarantee that every tree can be tiled, e.g.

```
mov t2, t1
add t3, t1
```

CS 412/413 Spring 2005

Introduction to Compilers

17

## More Handy Tiles

lea instruction computes a memory address

```
lea (t1,t2), t3
```

```
lea c1(t1,t2,c2), t3
```

CS 412/413 Spring 2005

Introduction to Compilers

18

## Matching Jump for RISC

- As defined in lecture, have
  - tjump(cond, destination)
  - fjump(cond, destination)
- Our tjump/fjump translates easily to RISC ISAs that have explicit comparison result

MIPS  
 cmplt t2, t3, t1  
 br t1, L

CS 412/413 Spring 2005

Introduction to Compilers

19

## Condition Code ISA

- Pentium: condition encoded in jump instruction
- cmp: compare operands and set flags
- jcc: conditional jump according to flags

set condition codes  
 cmp t1, t2  
 jl L  
 test condition codes

CS 412/413 Spring 2005

Introduction to Compilers

20

## Fixed-register instructions

mul r/m32

Multiply value in register eax  
 Result: low 32 bits in eax, high 32 bits in edx

jecxz L

Jump to label L if ecx is zero

add r/m32, %eax

Add to eax

- No fixed registers in low IR except frame pointer
- Need extra move instructions

CS 412/413 Spring 2005

Introduction to Compilers

21

## Implementation

- Maximal Munch: start from top node
- Find largest tile matching top node and all of the children nodes
- Invoke recursively on all children of tile
- Generate code for this tile
- Code for children will have been generated already in recursive calls
- How to find matching tiles?

CS 412/413 Spring 2005

Introduction to Compilers

22

## Matching Tiles

```

abstract class LIR_Stmt {
    Assembly munch();
}
class LIR_Assign extends LIR_Stmt {
    LIR_Expr src, dst;
    Assembly munch() {
        if (src instanceof IR_Plus &&
            ((IR_Plus)src).lhs.equals(dst) &&
            is_regmem32(dst) {
            Assembly e = ((LIR_Plus)src).rhs.munch();
            return e.append(new AddIns(dst,
                e.target()));
        }
        else if ...
    }
}
    
```

CS 412/413 Spring 2005

Introduction to Compilers

23

## Tile Specifications

- Previous approach simple, efficient, but hard-codes tiles and their priorities
- Another option: explicitly create data structures representing each tile in instruction set
  - Tiling performed by a generic tree-matching and code generation procedure
  - Can generate from instruction set description:
    - code generator generators
  - For RISC instruction sets, over-engineering

CS 412/413 Spring 2005

Introduction to Compilers

24

## How Good Is It?

- Very rough approximation on modern pipelined architectures: execution time is number of tiles
- Maximal munch finds a locally optimal (two adjacent tiles can never be combined into one) but not necessarily globally optimum tiling (least cost of all covers)
- Metric used: tile size

CS 412/413 Spring 2005

Introduction to Compilers

25

## Improving Instruction Selection

- Because it is greedy, Maximal Munch does not necessarily generate best code
  - Always selects largest tile, but not necessarily the fastest instruction
  - May pull nodes up into tiles inappropriately – it may be better to leave below (use smaller tiles above and larger, or faster tiles below)
- Better to use *dynamic programming*, an optimization technique that uses *memoization* to assure that subproblems are never solved more than once.

CS 412/413 Spring 2005

Introduction to Compilers

26

## Timing Cost Model

- **Idea:** associate cost with each tile (say proportional to number of cycles to execute)
  - may not be a good metric on modern architectures
- Total execution time is sum of costs of all tiles

CS 412/413 Spring 2005

Introduction to Compilers

27

## Finding globally optimum tiling

- **Goal:** find minimum total cost tiling of DAG
- **Algorithm:** for every node, find minimum total cost tiling of that node and subgraph below it
- **Lemma:** Given minimum cost tiling of all nodes in subgraph, we can find minimum cost tiling of the node by trying out all possible tiles matching the node
- **Therefore:** start from leaves, work upward to top node

CS 412/413 Spring 2005

Introduction to Compilers

28

## Dynamic Programming: a[i]

CS 412/413 Spring 2005

Introduction to Compilers

29

## Recursive Implementation

- Traverse DAG recursively, and for each node  $n$ , record  $\langle t, c \rangle$ , where
  - $t$  is the best tile to use for subgraph rooted at  $n$ ,
  - $c$  is the total cost of tiling the subgraph rooted at  $n$  if  $t$  is chosen.
- To compute  $\langle t, c \rangle$  for node  $n$ 
  - Consider every tile  $t'$  that matches rooted at  $n$ , and compute total cost  $c' = \text{cost of tile } t' + \text{sum of the costs of tiling the subgraphs rooted at the leaves of } t'$  (which costs can be computed recursively and memoized)
  - Store lowest-cost tile  $t'$  and its total cost  $c'$
- To emit code, traverse least-cost tiles recursively and emit code in postorder

CS 412/413 Spring 2005

Introduction to Compilers

30

## Memoization

```
class IR_Move extends IR_Stmt {
  IR_Expr src, dst;
  Assembly best; // initialized to null
  int optTileCost() {
    if (best != null) return best.cost();
    if (src instanceof IR_Plus &&
        ((IR_Plus)src).lhs.equals(dst) && is_regmem32(dst)) {
      int src_cost = ((IR_Plus)src).rhs.optTileCost();
      int cost = src_cost + CISC_ADD_COST;
      if (best == null || cost < best.cost())
        best = new AddIns(dst, e.target); }
    ...consider all other tiles...
    return best.cost();
  }
}
```

CS 412/413 Spring 2005

Introduction to Compilers

31

## Problems with Model

- Modern processors:
  - execution time not sum of tile times
  - instruction order matters
    - Processors pipeline instructions and execute different pieces of instructions in parallel
    - bad ordering (e.g. too many memory operations in sequence) stalls processor pipeline
    - processor can execute some instructions in parallel (super-scalar)
  - cost is merely an approximation
  - instruction scheduling needed

CS 412/413 Spring 2005

Introduction to Compilers

32

## Summary

- Can specify code generation process as a set of tiles that relate low IR trees (DAGs) to instruction sequences
- Instructions using fixed registers problematic but can be handled using extra temporaries
- Maximal Munch algorithm implemented simply as recursive traversal
- Dynamic programming algorithm generates better code, can be implemented recursively using memoization
- Real optimization will also require instruction scheduling
