Introduction to Compilers

Andrew Myers
Cornell University

Lecture 5: Top-down parsing

5 Feb 2016

Outline

- More on writing CFGs
- Top-down parsing
- LL(1) grammars
- Transforming a grammar into LL form
- Recursive-descent parsing - parsing made simple

Where we are

Source code
(character stream)

Token stream

if	(	b	==	0	)	a	=	b	;
----	---	---	----	---	---	---	---	---	---

Abstract syntax tree
(AST)

Lexical analysis

Syntactic Analysis
Parsing/build AST

Semantic Analysis

Review of CFGs

- Context-free grammars can describe programming-language syntax
- Power of CFG needed to handle common PL constructs (e.g., parens)
- String is in language of a grammar if derivation from start symbol to string
- Ambiguous grammars a problem

Top-down Parsing

- Grammars for top-down parsing
- Implementing a top-down parser (recursive descent parser)
- Generating an abstract syntax tree

Parsing Top-down

$$S \rightarrow E + S \mid E$$

$$E \rightarrow \text{num} \mid (S)$$

Goal: construct a leftmost derivation of string while reading in token stream

Partly-derived String	Lookahead	parsed part unparsed part
S	(	(1+2+(3+4))+5
$\rightarrow$ E +S	(	(1+2+(3+4))+5
$\rightarrow$ (S)+S	1	(1+2+(3+4))+5
$\rightarrow$ (E +S)+S	1	(1+2+(3+4))+5
$\rightarrow$ (1+ S)+S	2	(1+2+(3+4))+5
$\rightarrow$ (1+ E +S)+S	2	(1+2+(3+4))+5
$\rightarrow$ (1+2+ S)+S	2	(1+2+(3+4))+5
$\rightarrow$ (1+2+ E)+S	(	(1+2+(3+4))+5
$\rightarrow$ (1+2+(S))+S	3	(1+2+(3+4))+5
$\rightarrow$ (1+2+(E +S))+S	3	(1+2+(3+4))+5

Problem

$$S \rightarrow E + S \mid E$$
$$E \rightarrow \text{num} \mid (S)$$

- Want to decide which production to apply based on next symbol

$$(1) \quad S \rightarrow E \rightarrow (S) \rightarrow (E) \rightarrow (1)$$

$$(1)+2 \quad S \rightarrow E + S \rightarrow (S) + S \rightarrow (E) + S$$
$$\rightarrow (1)+E \rightarrow (1)+2$$

- *Why is this hard?*

Grammar is Problem

- This grammar cannot be parsed top-down with only a single look-ahead symbol
- Not **LL(1)**
- **Left-to-right-scanning, Left-most derivation, 1 look-ahead symbol**
 - Is it LL(k) for some k?
 - Can rewrite grammar to allow top-down parsing: create LL(1) grammar for same language

Making a grammar LL(1)

$S \rightarrow E + S$

$S \rightarrow E$

$E \rightarrow \text{num}$

$E \rightarrow (S)$

$S \rightarrow ES'$

$S' \rightarrow \varepsilon$

$S' \rightarrow + S$

$E \rightarrow \text{num}$

$E \rightarrow (S)$

- **Problem:** can't decide which S production to apply until we see symbol after first expression
- **Left-factoring:** Factor common S prefix, add new non-terminal S' at decision point. S' derives $(+E)^*$
- **Also:** convert left-recursion to right-recursion

Parsing with new grammar

$$S \rightarrow ES' \quad S' \rightarrow \varepsilon \mid + S \quad E \rightarrow \mathbf{num} \mid (S)$$

S	(	(1+2+(3+4))+5
$\rightarrow ES'$	(	(1+2+(3+4))+5
$\rightarrow (S)S'$	1	(1+2+(3+4))+5
$\rightarrow (ES')S'$	1	(1+2+(3+4))+5
$\rightarrow (1S')S'$	+	(1+2+(3+4))+5
$\rightarrow (1+ES')S'$	2	(1+2+(3+4))+5
$\rightarrow (1+2S')S'$	+	(1+2+(3+4))+5
$\rightarrow (1+2+S)S'$	(	(1+2+(3+4))+5
$\rightarrow (1+2+ES')S'$	(	(1+2+(3+4))+5
$\rightarrow (1+2+(S)S')S'$	3	(1+2+(3+4))+5
$\rightarrow (1+2+(ES')S')S'$	3	(1+2+(3+4))+5
$\rightarrow (1+2+(3S')S')S'$	+	(1+2+(3+4))+5
$\rightarrow (1+2+(3+ES')S')S'$	4	(1+2+(3+4))+5

Predictive Parsing

- **LL(1)** grammar:
 - for a given non-terminal, the look-ahead symbol uniquely determines the production to apply
 - top-down parsing = predictive parsing
 - Driven by *predictive parsing table* of non-terminals $\times$ input symbols $\rightarrow$ productions

Using Table

$S \rightarrow E S'$
$S' \rightarrow \varepsilon \mid + S$
$E \rightarrow \mathbf{num} \mid (S)$

S	(	(1+2+(3+4))+5
$\rightarrow \mathbf{E} S'$	(	(1+2+(3+4))+5
$\rightarrow (\mathbf{S}) S'$	1	(1+2+(3+4))+5
$\rightarrow (\mathbf{E} S') S'$	1	(1+2+(3+4))+5
$\rightarrow (1 \mathbf{S}') S'$	+	(1+2+(3+4))+5
$\rightarrow (1 + \mathbf{S}) S'$	2	(1+2+(3+4))+5
$\rightarrow (1 + \mathbf{E} S') S'$	2	(1+2+(3+4))+5
$\rightarrow (1 + 2 \mathbf{S}') S'$	+	(1+2+(3+4))+5

／ EOF

	num	+	(	)	\$
S	$\rightarrow E S'$		$\rightarrow E S'$		
S'		$\rightarrow +S$		$\rightarrow \varepsilon$	$\rightarrow \varepsilon$
E	$\rightarrow \mathbf{num}$		$\rightarrow (S)$		

How to Implement?

- Table can be converted easily into a ***recursive-descent parser***

	num	+	(	)	\$
S	$\rightarrow ES'$			$\rightarrow ES'$	
S'		$\rightarrow +S$			$\rightarrow \epsilon \rightarrow \epsilon$
E	$\rightarrow \text{num}$			$\rightarrow (S)$	

- Three procedures: `parse_S`, `parse_S'`, `parse_E`

Recursive-Descent Parser

```
void parse_S () {
    switch (token) {
        case num: parse_E(); parse_S'(); return;
        case '(': parse_E(); parse_S'(); return;
        default: throw new ParseError();
    }
}
```

lookahead token

Recursive-Descent Parser

```
void parse_S'() {
    switch (token) {
        case '+': token = input.read(); parse_S(); return;
        case ')': return;
        case EOF: return;
        default: throw new ParseError();
    }
}
```

number + () \$

S	$\rightarrow ES'$	$\rightarrow ES'$		
$\rightarrow S'$	$\rightarrow +S$	$\rightarrow \epsilon$	$\rightarrow \epsilon$	
E	$\rightarrow \text{number}$	$\rightarrow (S)$		

Recursive-Descent Parser

```
void parse_E() {
    switch (token) {
        case number: token = input.read(); return;
        case '(': token = input.read(); parse_S();
            if (token != ')') throw new ParseError();
            token = input.read(); return;
        default: throw new ParseError(); }
}
```

	number	+	(	)	\$
S	$\rightarrow ES'$		$\rightarrow ES'$		
S'		$\rightarrow +S$		$\rightarrow \epsilon$	$\rightarrow \epsilon$
$\rightarrow E$	$\rightarrow \text{number}$		$\rightarrow (S)$		

Call Tree = Parse Tree

$(1 + 2 + (3 + 4)) + 5$

How to Construct Parsing Tables

- Needed: algorithm for automatically generating a predictive parse table from a grammar

Constructing Parse Tables

- Can construct predictive parser if:

For every non-terminal, every look-ahead symbol can be handled by at most one production

- $FIRST(\gamma)$ for arbitrary string of terminals and non-terminals γ is:
 - set of symbols that might begin the fully expanded version of γ
- $FOLLOW(X)$ for a non-terminal X is:
 - set of symbols that might follow the derivation of X in the input stream

Parse Table Entries

- Consider a production $X \rightarrow \gamma$
- Add $\rightarrow \gamma$ to the X row for each symbol in $\text{FIRST}(\gamma)$

	num	+	(	)	\$
S	$\rightarrow ES'$		$\rightarrow ES'$		
S'		$\rightarrow +S$	$\rightarrow \epsilon$	$\rightarrow \epsilon$	
E	$\rightarrow \text{num}$		$\rightarrow (S)$		

- If γ can derive ϵ (γ is *nullable*), add $\rightarrow \gamma$ for each symbol in $\text{FOLLOW}(X)$
- Grammar is LL(1) if no conflicting entries

Computing nullable, FIRST

- X is nullable if it can derive the empty string:
 - if it derives ε directly ($X \rightarrow \varepsilon$)
 - if it has a production $X \rightarrow YZ\dots$ where all RHS symbols (Y, Z) are nullable
 - Algorithm: assume all non-terminals non-nullable, apply rules repeatedly until no change in status
- Determining $FIRST(\gamma)$
 - $FIRST(X) \supseteq FIRST(\gamma)$ if $X \rightarrow \gamma$
 - $FIRST(\mathbf{a} \beta) = \{ \mathbf{a} \}$
 - $FIRST(X \beta) \supseteq FIRST(X)$
 - $FIRST(X \beta) \supseteq FIRST(\beta)$ if X is nullable
 - **Algorithm:** Assume $FIRST(\gamma) = \{\}$ for all γ , apply rules repeatedly to build $FIRST$ sets.

Computing FOLLOW

- $FOLLOW(S) \supseteq \{ \$ \}$
 - If $X \rightarrow \alpha Y \beta$,
 $FOLLOW(Y) \supseteq FIRST(\beta)$
 - If $X \rightarrow \alpha Y \beta$ and β is nullable (or non-existent),
 $FOLLOW(Y) \supseteq FOLLOW(X)$
- **Algorithm:** Assume $FOLLOW(X) = \{ \}$ for all X , apply rules repeatedly to build $FOLLOW$ sets
- Common theme: iterative analysis. Start with initial assignment, apply rules until no change

Example

- nullable
 - only S' is nullable

- FIRST

- $FIRST(E S') = \{\mathbf{num}, (\}$
- $FIRST(+S) = \{+\}$
- $FIRST(\mathbf{num}) = \{\mathbf{num}\}$
- $FIRST((S)) = \{(\}$, $FIRST(S') = \{+\}$

- FOLLOW

- $FOLLOW(S) = \{\$,)\}$
- $FOLLOW(S') = \{\$,)\}$
- $FOLLOW(E) = \{+,), \$\}$

$$\begin{array}{l} S \rightarrow E S' \\ S' \rightarrow \varepsilon \mid + S \\ E \rightarrow \mathbf{num} \mid (S) \end{array}$$

Ambiguous grammars

- Construction of predictive parse table for ambiguous grammar results in *conflicts* (*but converse does not hold*)

$S \rightarrow S + S \mid S * S \mid \mathbf{num}$

$FIRST(S + S) = FIRST(S * S) = FIRST(\mathbf{num}) = \{ \mathbf{num} \}$

	num	+	*
S	$\rightarrow \mathbf{num}, \rightarrow S + S, \rightarrow S * S$		

Completing the parser

Now we know how to construct a recursive-descent parser for an LL(1) grammar.

LL(k) generalizes this to k lookahead tokens.

LL(k) parser generators can be used to automate the process (e.g. ANTLR)

Can we use recursive descent to build an abstract syntax tree too?

Creating the AST

```
abstract class Expr { }
```

```
class Add extends Expr {
```

```
    Expr left, right;
```

```
    Add(Expr L, Expr R) { left = L; right = R; }
```

```
}
```

```
class Num extends Expr {
```

```
    int value;
```

```
    Num (int v) { value = v);
```

```
}
```

AST Representation

$(1 + 2 + (3 + 4)) + 5$

How to generate this structure during recursive-descent parsing?

Creating the AST

- Just add code to each parsing routine to create the appropriate nodes!
- Works because parse tree and call tree have same shape
- `parse_S`, `parse_S'`, `parse_E` all return an `Expr`:

`void parse_E() ⇒ Expr parse_E()`

`void parse_S() ⇒ Expr parse_S()`

`void parse_S'() ⇒ Expr parse_S'()`

AST creation code

```
Expr parse_E() {  
    switch(token) {  
        case num: // E → number  
            Expr result = Num (token.value);  
            token = input.read(); return result;  
        case '(': // E → ( S )  
            token = input.read();  
            Expr result = parse_S();  
            if (token != ')') throw new ParseError();  
            token = input.read(); return result;  
        default: throw new ParseError();  
    }  
}
```

parse_S

```
Expr parse_S() {  
    switch (token) {  
        case num:  
        case '(':  
            Expr left = parse_E();  
            Expr right = parse_S'();  
            if (right == null) return left;  
            else return new Add(left, right);  
        default: throw new ParseError();  
    }  
}
```

$$\begin{array}{l} S \rightarrow E S' \\ S' \rightarrow \varepsilon \mid + S \\ E \rightarrow \mathbf{num} \mid (S) \end{array}$$

Or...an Interpreter!

$$\begin{aligned} S &\rightarrow E S' \\ S' &\rightarrow \varepsilon \mid + S \\ E &\rightarrow \mathbf{num} \mid (S) \end{aligned}$$

```
int parse_E() {
    switch(token) {
        case number:
            int result = token.value;
            token = input.read(); return result;
        case '(':
            token = input.read();
            int result = parse_S();
            if (token != ')') throw new ParseError();
            token = input.read(); return result;
        default: throw new ParseError(); }
}

int parse_S() {
    switch (token) {
        case number:
        case '(':
            int left = parse_E();
            int right = parse_S'();
            if (right == 0) return left;
            else return left + right;
        default: throw new ParseError(); } }
```

Summary

- We can build a recursive-descent parser for LL(1) grammars
 - Make parsing table from *FIRST*, *FOLLOW* sets
 - Translate to recursive-descent code
 - Instrument with abstract syntax tree creation
- Systematic approach avoids errors, detects ambiguities
- Next time: converting a grammar to LL(1) form, bottom-up parsing
