

CS419: Computer Networks

Lecture 4, Feb 14, 2004

IP Forwarding Table

Routing and Forwarding Revisited

CS419

- We separate notion of “routing” and “forwarding”
- Routing algorithm is what a router does in the “background” to figure out where each prefix should be forwarded
 - Address prefixes, next hops, link costs, distances, etc.
- Forwarding is what a router does when a packet arrives
 - Address prefixes, next hops, interface, subnet address

Routing and Forwarding Revisited

CS419

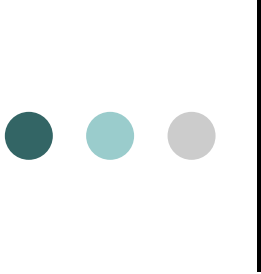

A simple example

CS419

addr	mask	Next Hop	iface	subnet addr
20.1.1.0	255.255.255.0	local	i1	X
20.1.2.0	255.255.255.0	local	i2	X
20.1.3.0	255.255.255.0	R2	i2	1:2:3:4:5:6

R1 forwarding table (FIB)

Simple (naïve) forwarding rule

CS419

- Step through table from top to bottom
- At each step, apply mask to FIB address and packet address. If results match, then use FIB entry to forward packet
 - If $(\text{FIB-addr} \& \text{FIB-mask}) ==$
 - $(\text{PK-addr} \& \text{FIB-mask})$
 - then use entry
- FIB = Forwarding Information Base
 - i.e. Forwarding Table
 - Routing Table also called RIB

addr	mask	Next Hop	iface	subnet addr
20.1.1.0	255.255.255.0	local	i1	x
20.1.2.0	255.255.255.0	local	i2	x
20.1.3.0	255.255.255.0	R2	i2	1:2:3:4:5:6

CS419

Simple example with default

20.1.1.0	255.255.255.0	i1
20.1.2.0	255.255.255.0	i2
20.1.3.0	255.255.255.0	R2
0.0.0.0	0.0.0.0	R2

But default entry must be last!

0.0.0.0	0.0.0.0	R2
20.1.1.0	255.255.255.0	i1
20.1.2.0	255.255.255.0	i2
20.1.3.0	255.255.255.0	R2

A more complex example (a site with 500 hosts)

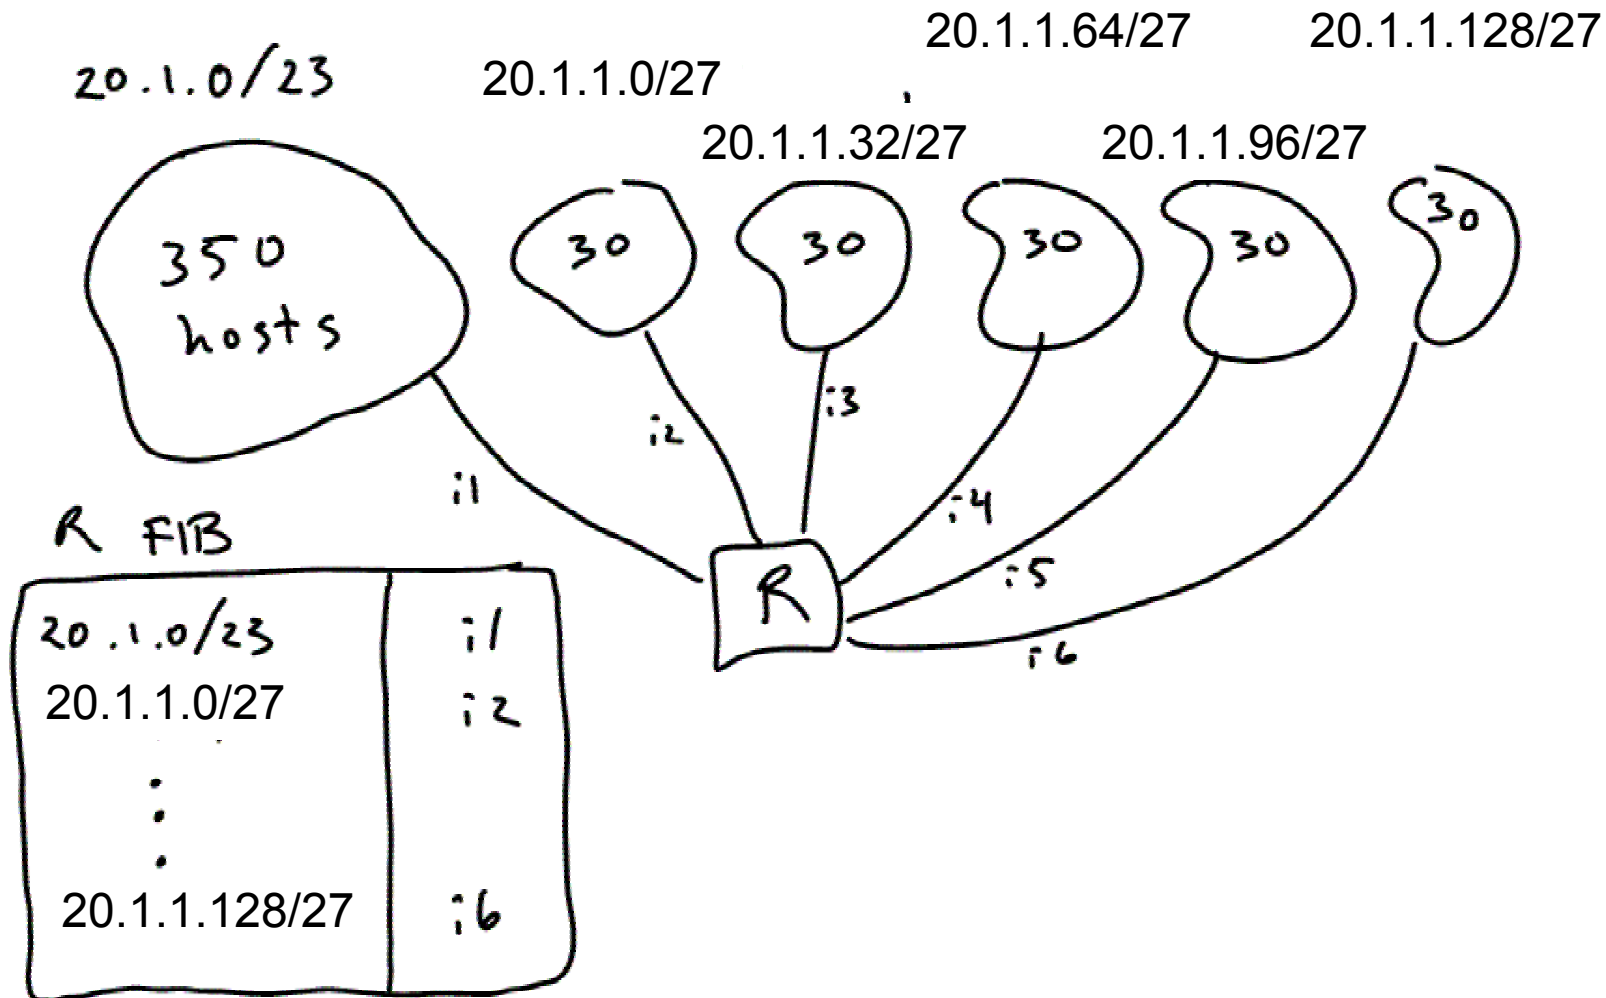

CS419

- How do we assign prefixes (addr and mask) in this case???

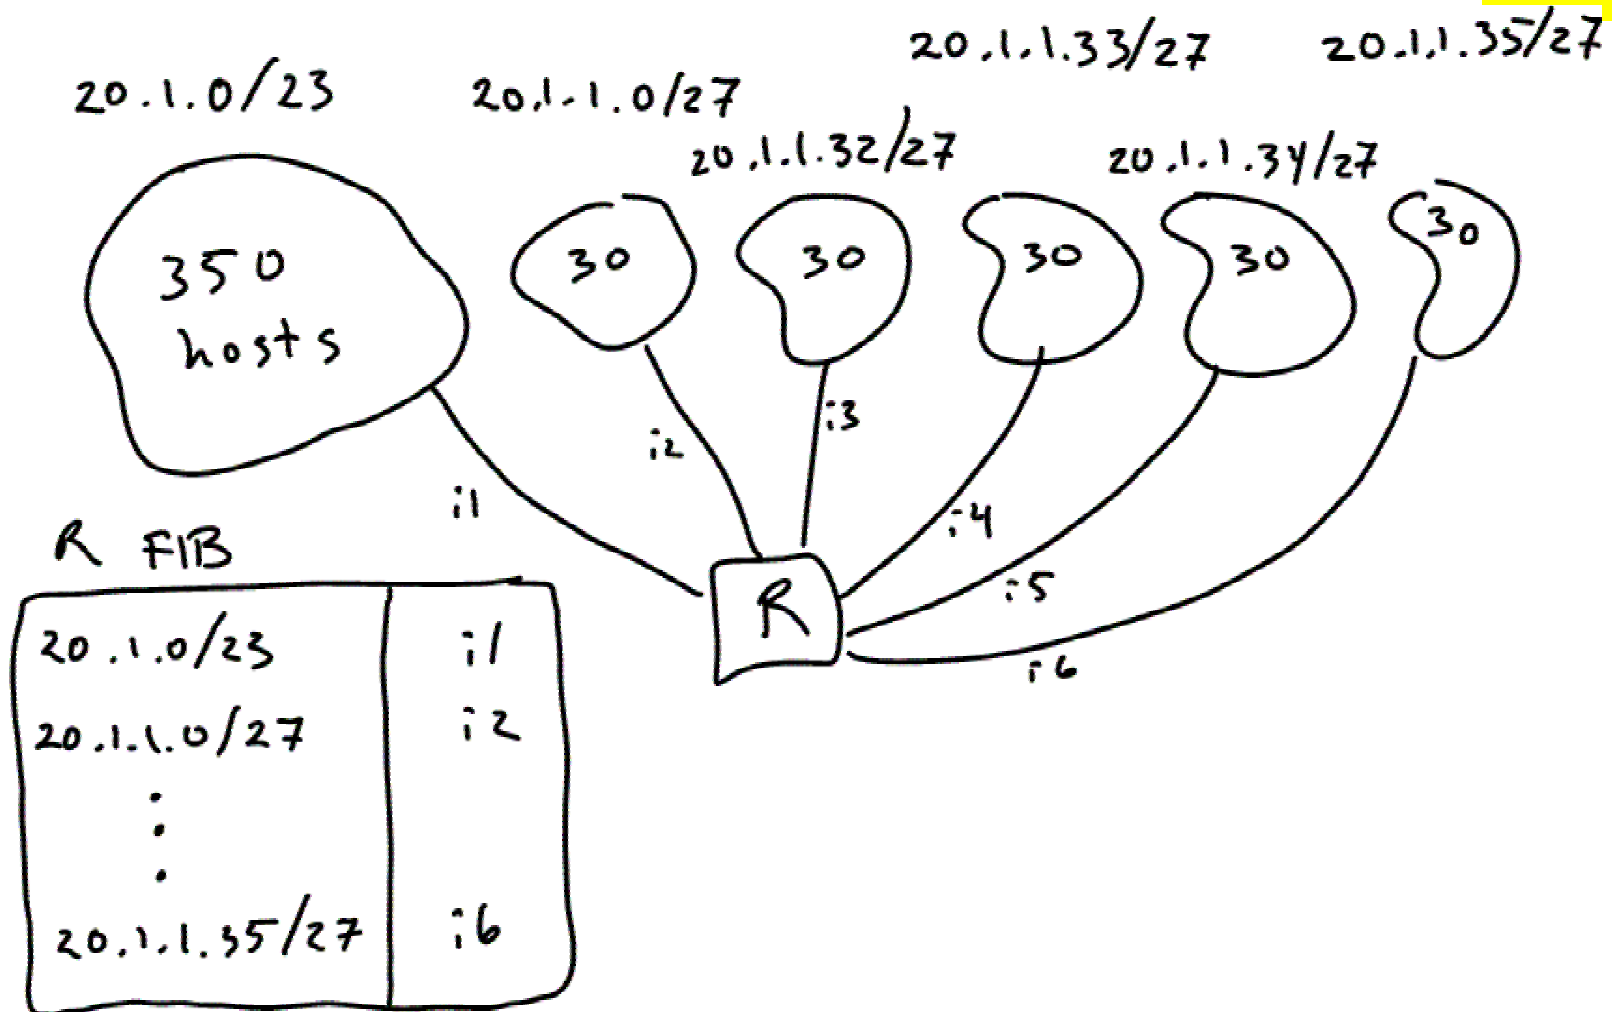

One way to assign prefixes...

CS419

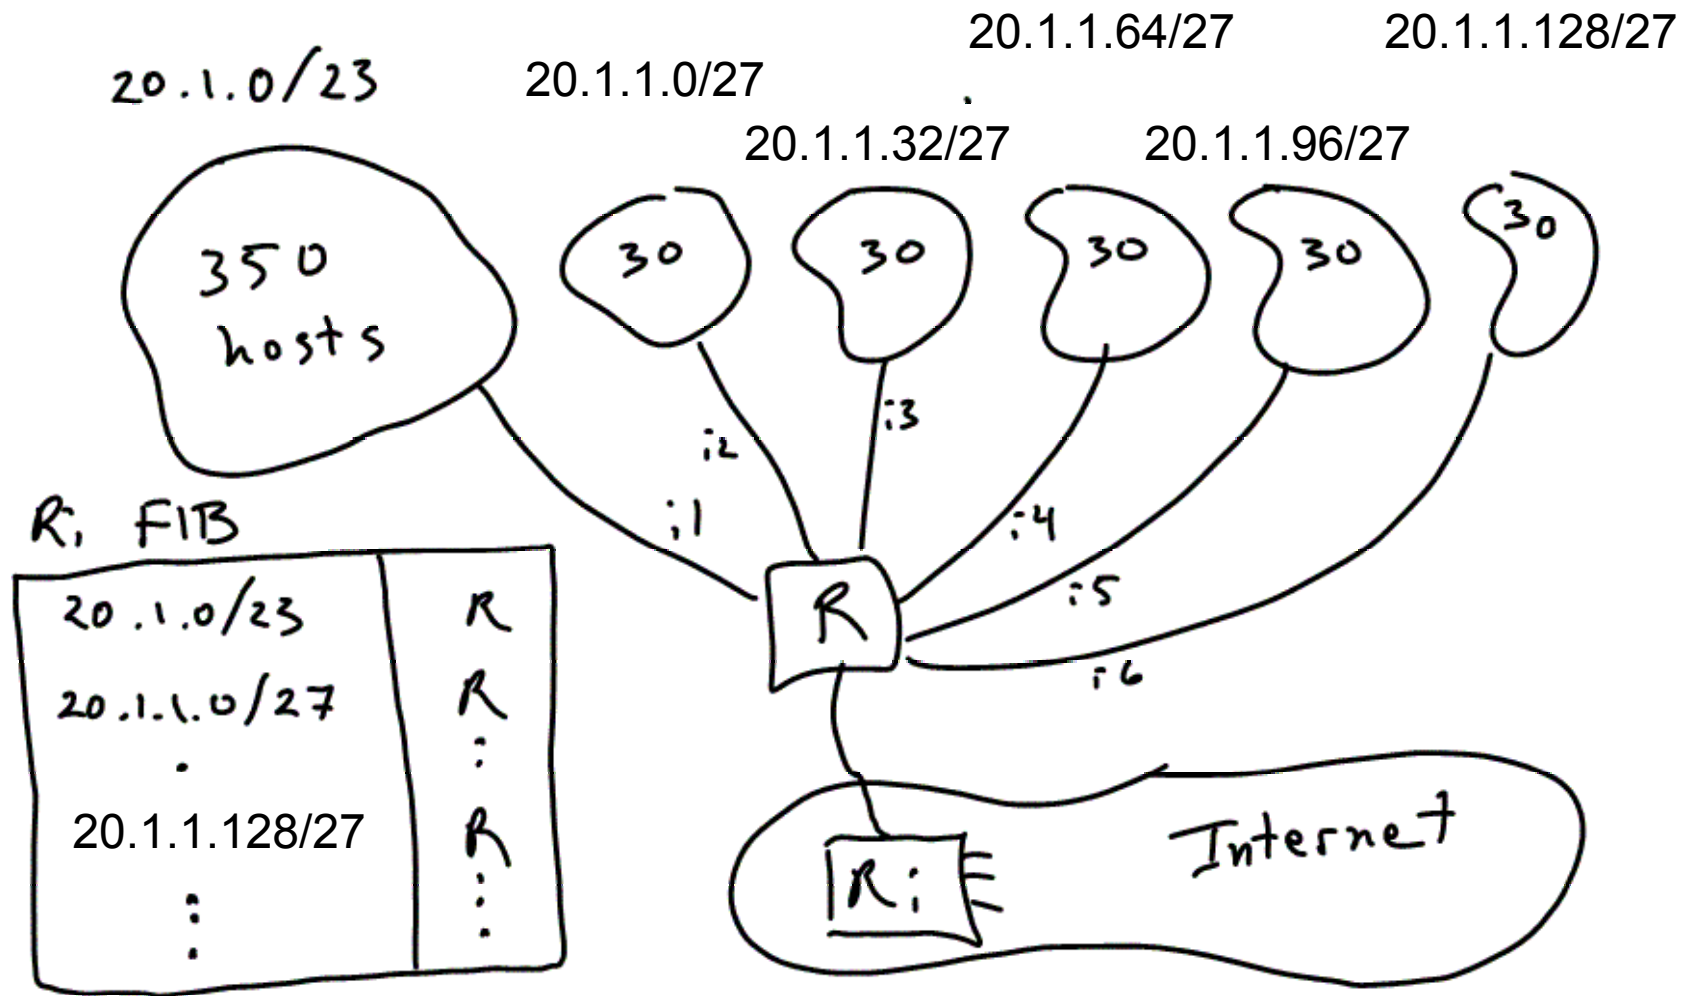

My mistake last year.....

CS419

The view from the global Internet: 6 FIB entries!

CS419

● ● ● | We can shrink that to one FIB entry!

CS419

R_i FIB

20.1.0/23	R
20.1.1.0/27	R
⋮	⋮
20.1.1.128/27	R
⋮	⋮

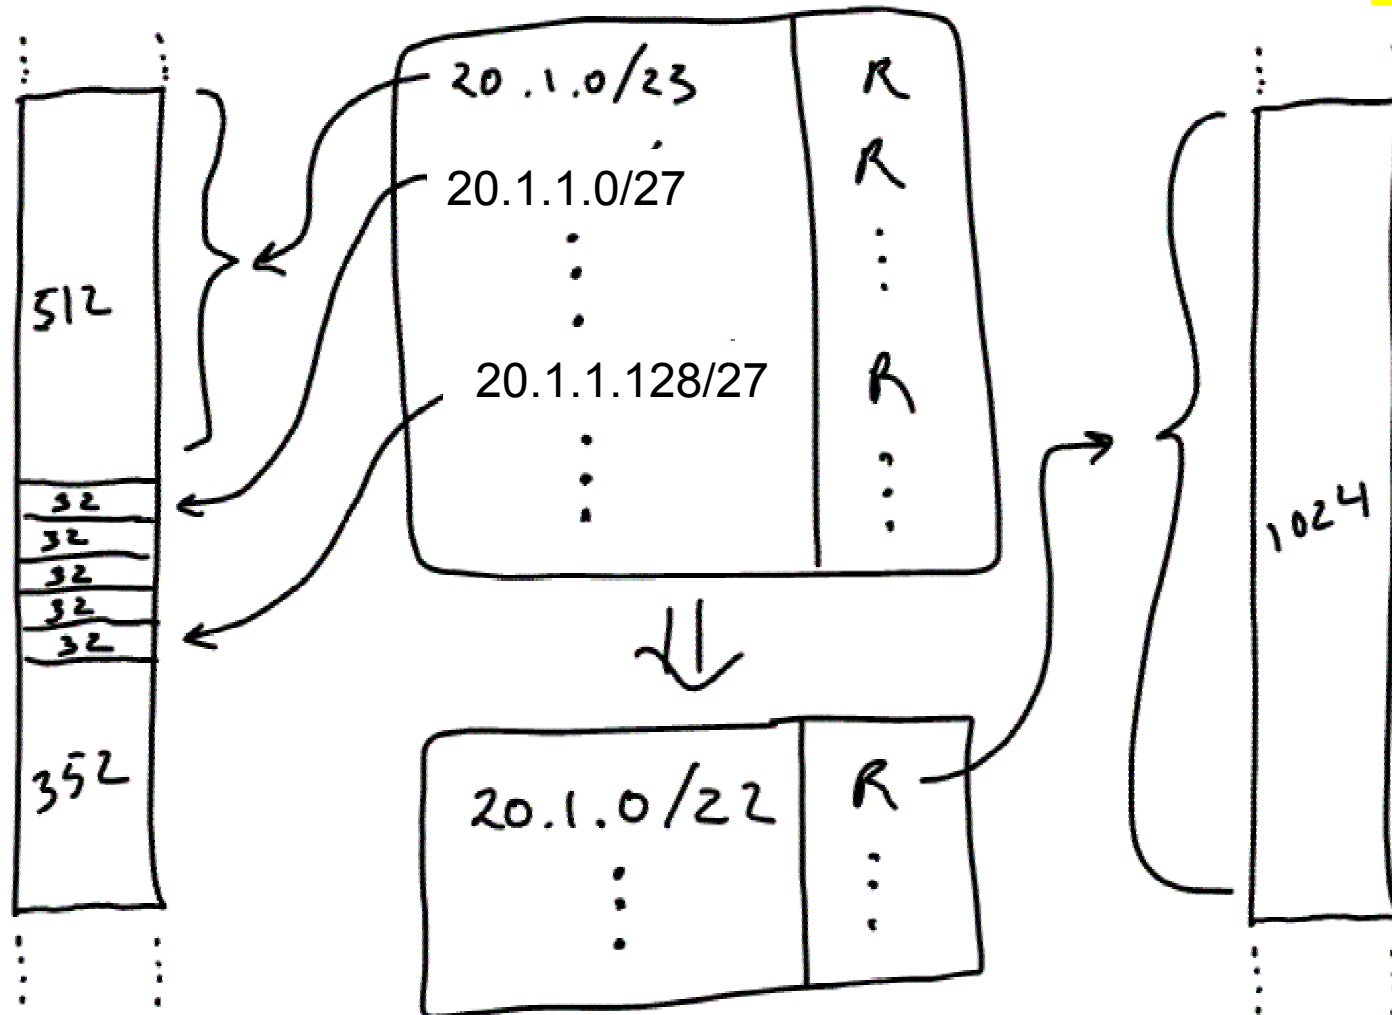

R_i FIB

20.1.0/22	R
⋮	⋮

1024 addresses to address 500 hosts! What a waste...

CS419

What about this prefix assignment approach instead?

CS419

Now 500 addresses fit into a 512 address block!

CS419

20.1.0/23	i1
20.1.1.0/27	i2
⋮	
20.1.1.128/27	i6

20.1.0/23	i1
20.1.0.0/27	i2
⋮	
20.1.0.128/27	i6

But now our forwarding rules fail (like with the default)

CS419

20.1.0/23	i1
20.1.0.0/27	i2
⋮	
20.1.0.128/27	i6

Longest-prefix match

CS419

- Since multiple entries may match, we prefer the entry with the longest mask (prefix)
- Two ways:
 1. Go through the whole FIB, remembering the matching entry with the longest prefix
 2. Sort FIB in order of longest prefix first, and select first match

First-match Longest-prefix

CS419

20.1.0/23	; 1
20.1.0.0/27	; 2
⋮	⋮
20.1.0.128/27	; 6

20.1.0.0/27	; 2
⋮	⋮
20.1.0.128/27	; 6
20.1.0/23	; 1

Best-match rules revisited

CS419

- Select matching FIB entry with longest prefix
- If multiple matching FIB entries have the same prefix size, then any may be used
 - Even simultaneously---path splitting for load balancing
 - But try to maintain source affinity (i.e. send different flows along different paths, but don't split a given flow)

Paths to multi-homed site X

CS419

Paths to Site X after X-B link failure

CS419

Better load balance (without increasing FIB size)

CS419

Paths to Site Y

CS419

Paths “to” Site Y after Y-B link failure

CS419

Implementing the forwarding table

CS419

- First-match style ok for small forwarding tables
 - Scales poorly with the number of entries
- Hash structures work for flat addresses, but not hierarchical (masked) addresses
 - “Bridged Ethernets”
- High-end routers implement forwarding table in hardware
 - Combination of a fancy tree structure and CAMs (Content Addressable Memory)
- Otherwise, some kind of tree-like data structure is typically used
 - We’ll look at this later in the course

Other types of forwarding

CS419

- What we looked at so far is *hop-by-hop* forwarding with *hierarchical addresses*
- Hop-by-hop means that every switch in the path makes an “independent” forwarding decision
- But we can also have *source routing*
 - The entire path is listed in the packet
 - IP has a (never used) option for this

Hop-by-hop versus source routing

CS419

- Source routing is (kindof) what you do when you print out directions from mapquest
 - I.e., you carry you path with you
- Hop-by-hop routing is often (kindof) how you find your way around Wal-Mart
 - “where is kids clothing?”, “where are socks?”

Hop-by-hop versus source routing

CS419

- Hop-by-hop is what is used in the Internet
 - Though many people have proposed source routing
- With the exception of routing through a switch fabric within a router
 - But we'll look at router/switch architecture later
