## Reduction from 3 SAT to MAX CUT

*CS 4820—March 2014* 

## David Steurer

**Problem (MAX CUT).** Given an undirected graph G with nonnegative edge capacities and a parameter  $c \in \mathbb{R}$ , decide if there exists a cut in G with capacity at least c.

The problem of deciding if there exists a cut with capacity at most c is called MIN CUT. This problem has a polynomial time algorithm (for example, using network flows). In contrast, no polynomial time algorithm is known for MAX CUT. The following theorem explains this situation.

**Theorem.** MAX CUT is NP-hard.

We prove the theorem by a chain of reductions. We reduce from 3-sat to NAE 4-sat to NAE 3-sat to MAX CUT. (The reason for going through NAE sat is that both MAX CUT and nae sat exhibit a similar kind of symmetry in their solutions.)

**Claim.** 3-sat reduces in polynomial time to NAE 4-SAT.

*Proof.* We will give a polynomial-time algorithm A that given a 3-sat instance constructs an equivalent NAE 4-sat instance. Given a 3-sat instance  $\varphi$ , the algorithm A constructs a NAE 4-sat instance  $\varphi' = A(\varphi)$  by adding a variable z to every clauses. (The variable z is distinct from the variables that appear in  $\varphi$ .) For example, the 3-sat clause  $x_1 \vee x_3 \vee \neg x_4$  would be replaced by the NAE 4-sat clause NAE $(x_1, x_3, \neg x_4, z)$ .

We are to show that  $\varphi$  is satisfiable if and only if  $\varphi'$  is satisfiable. If  $x_1, \ldots, x_n$  is a satisfying assignment for  $\varphi$ , then the same assignment satisfies  $\varphi$  when we choose z = 0.2 The reason is the following identity,

$$a \lor b \lor c = \text{NAE}(a, b, c, 0)$$

(In words, a disjunction of terms is true if and only not all terms are equal to 0.) To show the other direction, suppose  $x_1, ..., x_n, z$  is a satisfying assignment of  $\varphi'$ . Notice that  $\neg x_1, ..., \neg x_n, \neg z$  is also a satisfying assignment of  $\varphi'$  (because NAE(a, b, c, d) = NAE( $\neg a, \neg b, \neg c, \neg d$ )). In one of these two assignments, the value assigned to the variable z is 0. This assignment corresponds to a satisfying assignment for  $\varphi$  (again using the identity above).

**Claim.** NAE 4-SAT reduces in polynomial time to NAE 3-SAT.

*Proof.* Given an NAE 4-SAT instance  $\varphi$ , we will construct an equivalent NAE 3-SAT instance  $\varphi'$  by splitting every NAE 4-SAT clause  $C_i^{(1)} = \text{NAE}(a,b,c,d)$  in  $\varphi$  into two NAE 3-SAT clauses  $C_i^{(2)} = \text{NAE}(a,b,w_i)$  and  $C_i^2 = \text{NAE}(\neg w_i,c,d)$  that are linked together by an additional new variable  $w_i$ .

The correctness of the reduction follows from the following fact: Four Boolean values a, b, c, d are not all equal if and only if there exists a Boolean value w such that NAE(a, b, w) and NAE $(\neg w, c, d)$ .

<sup>&</sup>lt;sup>1</sup>Here, NAE is the Boolean operation that evaluates to TRUE if and only if not all of its inputs are equal.

<sup>&</sup>lt;sup>2</sup>We use 0 and 1 to abbreviate the Boolean values false and true.

<sup>&</sup>lt;sup>3</sup>I only know how to verify this fact by a somehwat cumbersome case distinction.

Claim. NAE 3-SAT reduces in polynomial time to MAX CUT.

*Proof.* Given a NAE 3-SAT instance  $\varphi$ , we will construct an equivalent MAX CUT instance (G,c). For every variable  $x_i$  of  $\varphi$ , we will add two vertices to G labeled by  $x_i$  and  $\neg x_i$  and we will connect the two vertices by an edge. We assign capacity  $M = 10 \cdot m$  to each of these "variable" edges. (Here, m is the number of clauses in  $\varphi$  and n is the number of variabes.) For every clause C in  $\varphi$ , we will add a "clause" triangle between the vertices corresponding to the terms in C. We assign capacity 1 to each of these "clause" edges.

We claim that *G* contains a cut with capacity at least  $n \cdot M + 2 \cdot m$  if and only if  $\varphi$  is satisfiable.

Suppose  $\varphi$  is satisfiable and consider any satisfying assignment. This assignment corresponds to a cut in G. (One side of the cut consists of all vertices labeled by terms that evaluate to 1 in the assignment. The other side of the cut consists of all vertices labeled by terms that evaluate to 0 in the assignment.) Since exactly one of terms  $x_i$  and  $\neg x_i$  evalute to 1 in an assignment, all variable edges go across the cut, which contributes  $n \cdot M$  to the capacity of the cut. Since the assignment satisfies  $\varphi$ , exactly two edges in every clause triangle go across the cut, which contributes  $2 \cdot m$  to the capacity of the cut. In total the capacity of the cut is equal to  $n \cdot M + 2 \cdot m$ .

On the other, suppose that G contains a cut with capacity at least  $n \cdot M + 2 \cdot m$ . First, we claim that all variable edges go across this cut. The reason is that any cut that misses at least one of the variable edges has capacity at most  $(n-1) \cdot M + 3 \cdot m = n \cdot M + 3 \cdot m - 10m$ , which is strictly smaller than  $n \cdot M + 2m$ . Next, we claim that exactly two edges of every clause triangle go across the cut. The reason is that no cut can separate three edges of a triangle and therefore if a cut separates fewer than two edges in one of clause triangles, then its capacity is strictly smaller than  $n \cdot M + 2m$ . Since all variable edge go across, this cut corresponds to an assignment for  $\varphi$ . Furthermore, since the cut separates exactly two edges per clause triangle, the corresponding assignment satisfies all clauses of  $\varphi$ .

<sup>&</sup>lt;sup>4</sup>In this description, we assume that every clause contains three distinct variables. This assumption can be justified by a preprocessing step. Alternatively, we can modify the reduction slightly to accommodate such clauses.
