Lecture 17: Mandatory Access Control

CS 5430

3/26/2018

Review: Access control

- Subject: principal to which execution can be attributed
- Object: data or resource
- Operation: performed by subject on object
- Right: entitlement to perform operation

Review: DAC

- Discretionary access control (DAC)
 - Philosophy: users have the *discretion* to specify policy themselves
 - Commonly, information belongs to the owner of object
 - Model: access control relation
 - Set of triples (subj,obj,rights)
 - Sometimes described as access control "matrix"

Implementations:

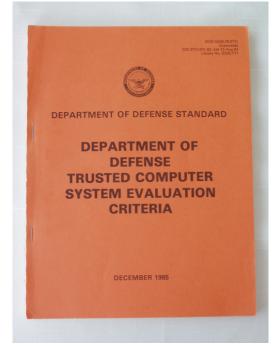

- Access control lists (ACLs): each object associated with list of (subject, rights)
- Capability lists (Privilege lists): each subject associated with list of (object, rights)
- Capabilities: distributed ways of implementing privilege lists

MAC

- Mandatory access control (MAC)
 - not Message Authentication Code (applied crypto), nor Media Access Control (networking)
 - **philosophy:** central authority *mandates* policy
 - information belongs to the authority, not to the individual users

Multi-Level Security

- A mechanism for monitoring access control in a system where both principals and objects have security labels drawn from a hierarchy of labels
- Commonly associated with military systems
- Influenced "Orange Book" (DoD Trusted Computer System Evaluation Criteria)
 - A) Verified Protection
 - **B) Mandatory Protection**
 - C) Discretionary Protection
 - D) Minimal Protection

Sensitivity

- Concern is confidentiality of information
- Documents classified according to sensitivity: risk associated with release of information
- In US:
 - Top Secret
 - Secret
 - Confidential
 - Unclassified

Compartments

- Documents classified according to compartment(s): categories of information (in fact, aka category)
 - cryptography
 - nuclear
 - biological
 - reconnaissance
- Need to Know Principle: access should be granted only when necessary to perform assigned duties (instance of Least Privilege)
 - {crypto, nuclear}: must need to know about both to access
 - {}: no particular compartments

Labels

- Label: pair of sensitivity level and set of compartments, e.g.,
 - (Top Secret, {crypto, nuclear})
 - (Unclassified, {})
- Users are labeled according to their clearance
- Document is labeled aka classified
 - Perhaps each paragraph labeled
 - Label of document is most restrictive label for any paragraph
- Labels are imposed by organization
- Notation: let L(X) be the label of entity X

Restrictiveness of labels

Notation: $L1 \sqsubseteq L2$

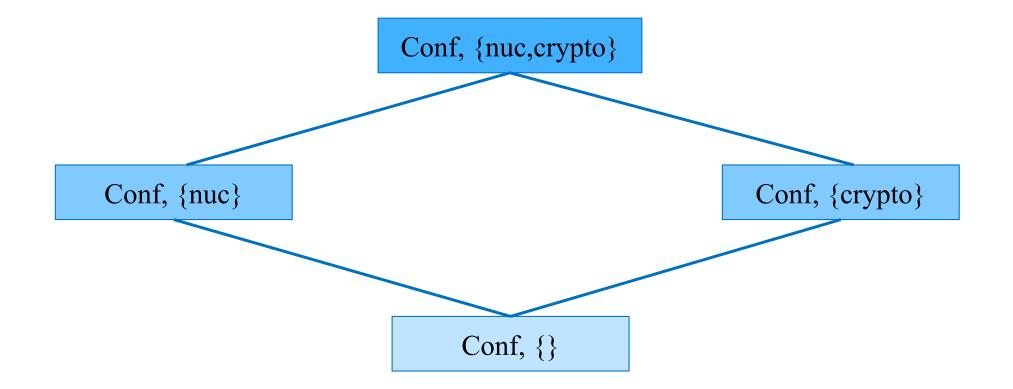

- means L1 is no more restrictive than L2
 - less precisely: L1 is less restrictive than L2

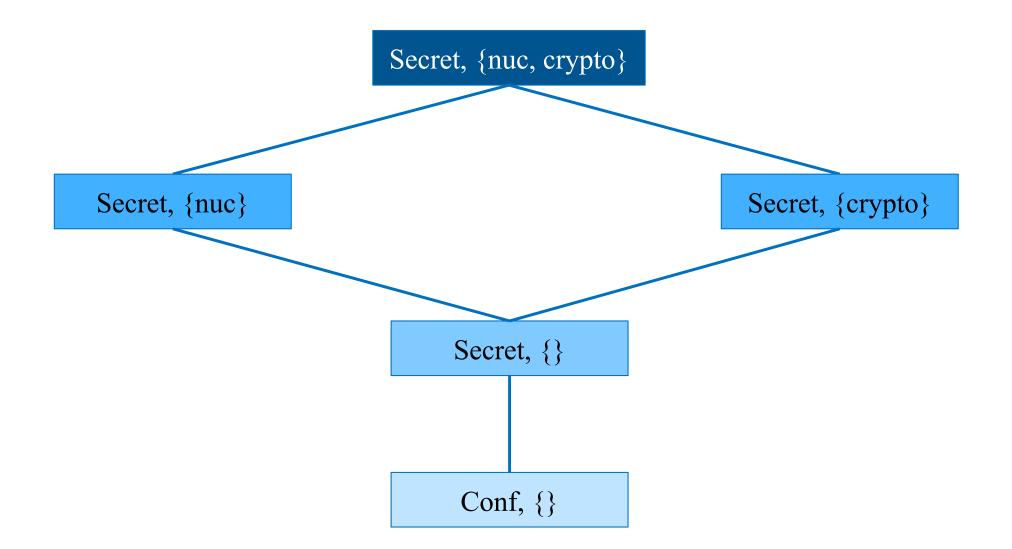

Definition:

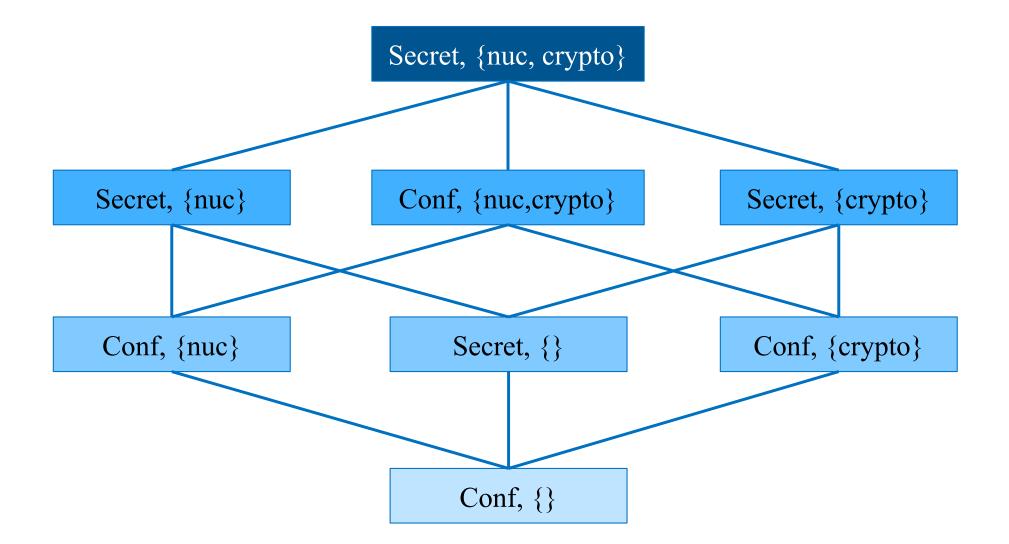

- Let L1 = (S1, C1) and L2 = (S2, C2)
- L1 \sqsubseteq L2 iff S1 \leq S2 and C1 \subseteq C2
- Where ≤ is order on sensitivity: Unclassified ≤ Confidential ≤ Secret ≤ Top Secret

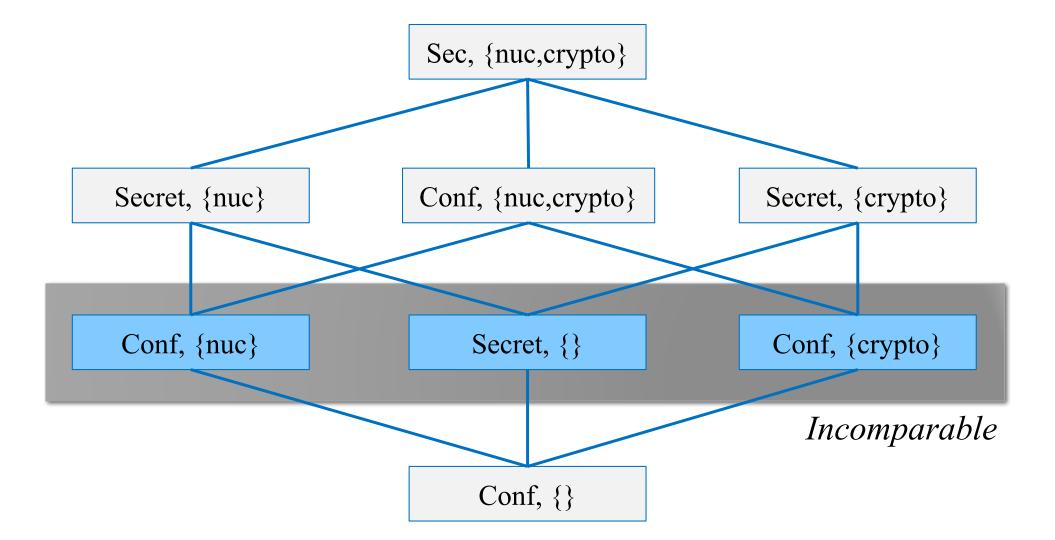

• e.g.

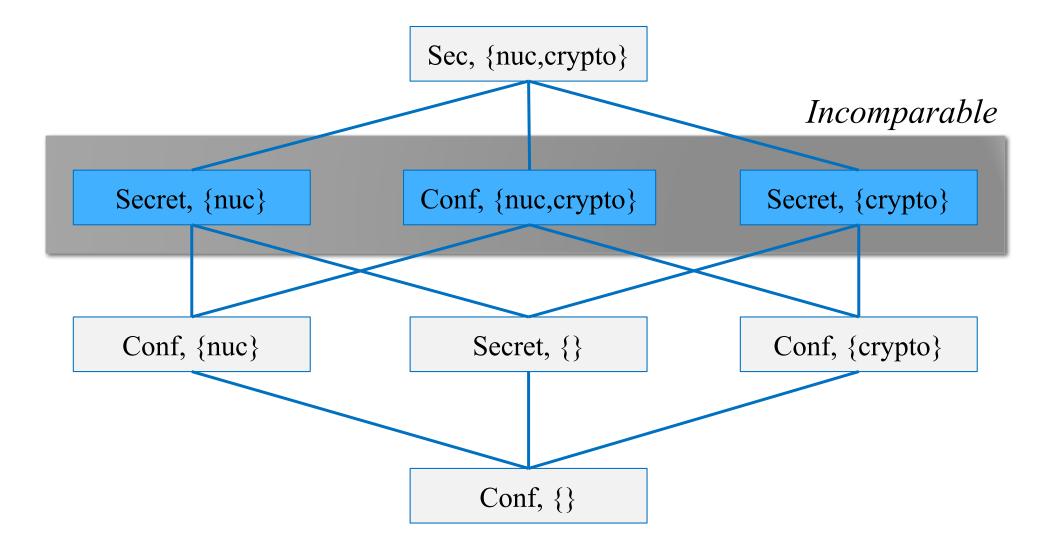

- (Unclassified,{}) ⊑ (Top Secret, {})
- (Top Secret, {crypto})
 (Top Secret, {crypto,nuclear})

Access control with MLS

- When may a subject read an object?
 - Threat: subject attempts to read information for which it is not cleared
 - e.g., subject with clearance Unclassified attempts to read Top Secret information
- When may a subject write an object?
 - Threat: subject attempts to *launder* information by writing into a lower-security object
 - e.g., subject with clearance Top Secret reads Top Secret information then writes it into an Unclassified file

Access control with MLS

- Users trustworthy by virtue of vetting process for security clearance
- Out of scope (e.g.): user who views Top Secret information and calls the Washington Post
- But still want to enforce Least Privilege
- And malicious programs are a threat...

Trojan Horse

Access control with MLS

- When may a subject read an object?
 - S may read O iff L(O) ⊑ L(S)
 - object's classification must be below (or equal to) subject's clearance
 - "no read up"
- When may a subject write an object?
 - S may write O iff L(S) ⊑ L(O)
 - object's classification must be above (or equal to) subject's clearance
 - "no write down"
- Beautiful symmetry between these

Reading with MLS

- Scenario:
 - Colonel with clearance (Secret, {nuclear, Europe})
 - DocA with classification (Confidential, {nuclear})
 - DocB with classification (Secret, {Europe, US})
 - DocC with classification (Top Secret, {nuclear, Europe})
- Which documents may Colonel read?
 - Recall: S may read O iff L(O)
 L(S)
 - DocA: (Confidential, {nuclear})
 (Secret, {nuclear, Europe})

Writing with MLS

- Scenario:
 - Colonel with clearance (Secret, {nuclear, Europe})
 - DocA with classification (Confidential, {nuclear})
 - DocB with classification (Secret, {Europe, US})
 - DocC with classification (Top Secret, {nuclear, Europe})
- Which documents may Colonel write?
 - Recall: S may write O iff $L(S) \sqsubseteq L(O)$

Reading and writing with MLS

Scenario:

- Colonel with clearance (Secret, {nuclear, Europe})
- DocA with classification (Confidential, {nuclear})
- DocB with classification (Secret, {Europe, US})
- DocC with classification (Top Secret, {nuclear, Europe})
- Summary:
 - DocA: Colonel may read but not write
 - DocB: Colonel may neither read nor write
 - DocC: Colonel may write but not read

Prevention of laundering

- Earlier concern: "subject with clearance Top Secret reads Top Secret information then writes it into an Unclassified file"
- More generally:
 - S reads O1 then writes O2
 - where $L(O2) \sqsubset L(O1)$
 - and regardless of L(S)
- Prohibited by MLS rules:
 - S read O1, so $L(O1) \sqsubseteq L(S)$
 - S wrote O2, so $L(S) \sqsubseteq L(O2)$
 - So $L(O1) \sqsubseteq L(S) \sqsubseteq L(O2)$
 - Hence L(O1) ⊑ L(O2)
 - But combined with L(O2) □ L(O1), we have L(O1) □ L(O1)
 - Contradiction!
- So access control rules would defeat laundering, Trojan Horse, etc.

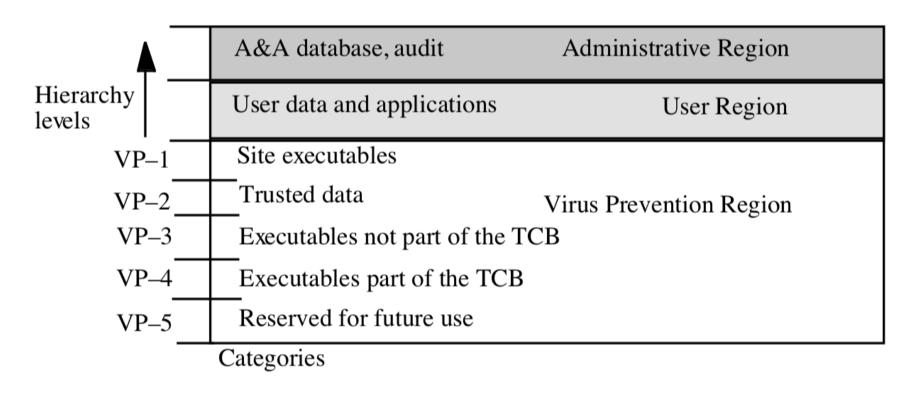

Perplexities of writing with MLS

- 1. Blind write: subject may not read higher-security object yet may write it
 - Useful for logging
 - Some implementations prohibit writing up as well as writing down
- 2. **User** who wants to write lower-security object may not
 - Attenuation of privilege: login at a lower security level than clearance
 - Motivated by Trojan Horse
 - Nice (annoying?) application of Least Privilege
- 3. Declassification violates "no write down"
 - Encryption or billing procedure produces (e.g.) Unclassified output from Secret information
 - Traditional solution is trusted subjects who are not constrained by access control rules

DG/UX

- Discontinued Unix OS, release 1985
- Three regions:

Virus Protection \Box User Region \Box Administrative Region

DG/UX

- Discontinued Unix OS, release 1985
- Three regions:
 Virus Protection

 User Region

 Administrative Region
- MLS confidentiality: read down, no read up
- Extra integrity: no write down, no write up
 - for shared directories (e.g., /tmp), introduced mulit-level directories with one hidden subdirectory for each level

SELinux

- Kernel security module, dates back to NSA c. 2000, merged with Linux kernel mainline in 2.6
- Goal: separate security policy from security decisions

- Supports mandatory access controls in reference policy.
 When MLS is enabled:
 - Each principal (user or process) is assigned a context (username, role, domain, (sensitivity))
 - Each object (file, port, hardware) is assigned a context
 - SELinux enforces MLS

TrustedBSD [2000]

- Similar goals to SELinux: separate policy from security mechanism, implements MLS
- ported parts of SELinux to FreeBSD
- Many components eventually folded into FreeBSD
- Most interfaces supported on Macs since OSX 10.5

Formalizing MLS

[Bell and LaPadula 1973]

- Formal mathematical model of MLS plus access control matrix
- Proof that information cannot leak to subjects not cleared for it
- "No read up": simple security property
- "No write down": *-property
- "The influence of [BLP] permeates all policy modeling in computer security" –Matt Bishop
 - Influenced Orange Book
 - Led to research field "foundations of computer security"

BLP, for integrity

- BLP is about confidentiality
- Adapted to integrity by Biba [1977]: same rules, different lattice
 - Instead of Unclassified and Secret, labels could be Untrusted and Trusted
- L1
 L2 means "L1 may flow to L2 without breaking confidentiality"
 - BLP: low secrecy sources may flow to high secrecy sinks
 - Hence Unclassified
 Secret, but not v.v.
 - Biba: low integrity sources may not flow to high integrity sinks
 - Hence Trusted
 Untrusted, but not v.v.
 - High vs. low is "flipped" (lattices are *duals*)

Biba model

S may read O iff L(O) ⊑ L(S)

- E.g., Trusted subject cannot read Untrusted object
- But Untrusted subject may read Trusted object

S may write O iff L(S) ⊑ L(O)

- E.g., Trusted subject may write Untrusted object
- But Untrusted subject may not write Trusted object

Beyond Multi-level Security...

Mandatory access control comes in many different forms (not just MLS):

- 1. Brewer-Nash (consulting firm)
- 2. Clark-Wilson (business)
- 3. Role-based access control (organization)
- 4. Clinical information systems (medicine)
