Abstract

We present a propositional logic to reason about the uncertainty of events, where the uncertainty is modeled by a set of probability measures assigning an interval of probability to each event. We give a sound and complete axiomatization for the logic, and show that the satisfiability problem is NP-complete, no harder than satisfiability for propositional logic.

1. Introduction

Various measures exist that attempt to quantify uncertainty. For many trained in the use of probability theory, probability measures are an obvious choice. However, probability cannot easily capture certain situations of interest. Consider a simple example: suppose we have a bag of 100 marbles; we know 30 are red and we know the remaining 70 are either blue or yellow, although we do not know the exact proportion of blue and yellow. If we are modeling the situation where we pick a ball from the bag at random, we need to assign a probability to three different events: picking up a red ball (*red-event*), picking up a blue ball (*blue-event*), and picking up a yellow ball (*yellow-event*). We can clearly assign a probability of .3 to *red-event*, but there is no clear probability to assign to *blue-event* or *yellow-event*.

One way to approach this problem is to represent the uncertainty using a set of probability measures, with a probability measure for each possible proportion of blue and yellow balls. For instance, we could use the set of probabilities $\mathcal{P} = \{\mu_\alpha : \alpha \in [0, .7]\}$, where μ_α gives *red-event* probability .3, *blue-event* probability α , and *yellow-event* probability $.7 - \alpha$. To any set of probabilities \mathcal{P} we can assign a pair of functions, the upper and lower probability measure, that for an event X give the supremum (respectively, the infimum) of the probability of X according to the probability measures in \mathcal{P} . These measures can be used to deal with uncertainty in the manner described above, where the lower and upper probability of an event defines a range of probability for that event.¹ (This example can be viewed as giving a frequentist interpretation of upper probabilities. Upper probabilities can also be given a subjective interpretation, for example, by considering the odds at which someone would be willing to accept or reject a bet (Smith, 1961; Walley, 1991).)

1. Note that using sets of probability measures is not the only way to model this situation. An alternative approach, using inner measures, is studied by Fagin and Halpern (1991).

Given a measure of uncertainty, one can define a logic for reasoning about it. Fagin, Halpern and Megiddo (1990) (FHM from now on) introduce a logic for reasoning about probabilities, with a possible-worlds semantics that assigns a probability to each possible world. They provide an axiomatization for the logic, which they prove sound and complete with respect to the semantics. They also show that the satisfiability problem for the logic, somewhat surprisingly, is NP-complete, and hence no harder than the satisfiability problem for propositional logic. They moreover show how their logic can be extended to other notions of uncertainty, such as inner measures (Fagin & Halpern, 1991) and Dempster-Shafer belief functions (Shafer, 1976).

In this paper, we describe a logic for reasoning about upper probability measures, along the lines of the FHM logic. The logic allows reasoning about linear inequalities involving upper probabilities measures. Like the logics considered in FHM, our logic is agnostic as to the interpretation of upper probabilities, whether frequentist or subjectivist. The main challenge is to derive a provably complete axiomatization of the logic; to do this, we need a characterization of upper probability measures in terms of properties that can be expressed in the logic. Many semantic characterizations of upper probability measures have been proposed in the literature. The characterization of Anger and Lembcke (1985) turns out to be best suited for our purposes. Even though we are reasoning about potentially infinite sets of probability measures, the satisfiability problem for our logic remains NP-complete. Intuitively, we need guess only a small number of probability measures to satisfy any given formula, polynomially many in the size of the formula. Moreover, these probability measures can be taken to be defined on a finite state space, again polynomial in the size of the formula. Thus, we need to basically determine polynomially many values—a value for each probability measure at each state—to decide the satisfiability of a formula.

The rest of this paper is structured as follows. In Section 2, we review the required material from probability theory and the theory of upper probabilities. In Section 3, we present the logic and an axiomatization. In Section 4, we prove that the axiomatization is sound and complete with respect to the natural semantic models expressed in terms of upper probability spaces. Finally, in Section 5, we prove that the decision problem for the logic is NP-complete. The proofs of the new, more technical results are given in Appendix A. To make the paper self-contained, we also review Anger and Lembcke’s results in Appendix B.

2. Characterizing Upper Probability Measures

We start with a brief review of the relevant definitions. Recall that a probability measure is a function $\mu : \Sigma \rightarrow [0, 1]$ for Σ an algebra of subsets of Ω (that is Σ is closed under complements and unions), satisfying $\mu(\emptyset) = 0$, $\mu(\Omega) = 1$, and $\mu(A \cup B) = \mu(A) + \mu(B)$ for all disjoint sets A, B in Σ .² A probability space is a tuple (Ω, Σ, μ) , where Ω is a set, Σ is an algebra of subsets of Ω (the measurable sets), and μ is a probability measure defined on Σ . Given a set \mathcal{P} of probability measures, let \mathcal{P}^* be the upper probability measure defined

2. If Ω is infinite, we could also require that Σ be a σ -algebra (i.e., closed under countable unions) and that μ be countably additive. Requiring countable additivity would not affect our results, since we show that we can take Ω to be finite. For ease of exposition, we have not required it.

by $\mathcal{P}^*(X) = \sup\{\mu(X) : \mu \in \mathcal{P}\}$ for $X \in \Sigma$.³ Similarly, $\mathcal{P}_*(X) = \inf\{\mu(X) : \mu \in \mathcal{P}\}$ is the lower probability of $X \in \Sigma$. A straightforward derivation shows that the relationship $\mathcal{P}_*(X) = 1 - \mathcal{P}^*(\bar{X})$ holds between upper and lower probabilities, where \bar{X} is the complement of X in Ω . Because of this duality, we restrict the discussion to upper probability measures in this paper, with the understanding that results for lower probabilities can be similarly derived. Finally, an *upper probability space* is a tuple $(\Omega, \Sigma, \mathcal{P})$ where \mathcal{P} is a set of probability measures on Σ .

We would like a set of properties that completely characterizes upper probability measures. In other words, we would like a set of properties that allow us to determine if a function $f : \Sigma \rightarrow \mathbb{R}$ (for an algebra Σ of subsets of Ω) is an upper probability measure, that is, whether there exists a set \mathcal{P} of probability measures such that for all $X \in \Sigma$, $\mathcal{P}^*(X) = f(X)$.⁴

One approach to the characterization of upper probability measures is to adapt the characterization of Dempster-Shafer belief functions; these functions are known to be the lower envelope of the probability measures that dominate them, and thus form a subclass of the class of lower probability measures. By the duality noted earlier, a characterization of lower probability measures would yield a characterization of upper probability measures. The characterization of belief functions is derived from a generalization of the following inclusion-exclusion principle for probabilities (obtained by replacing the equality with an inequality):

$$\mu\left(\bigcup_{i=1}^n A_i\right) = \sum_{i=1}^n (-1)^{i-1} \left(\sum_{\substack{J \subseteq \{1, \dots, n\} \\ |J|=i}} \mu\left(\bigcap_{j \in J} A_j\right) \right).$$

It seems reasonable that a characterization of lower (or upper) probability measures could be derived along similar lines. However, as is well known, most properties derivable from the inclusion-exclusion principle (which include most of the properties reported in the literature) are insufficient to characterize upper probability measures. Huber (1981, p. 257) and Walley (1991, p. 85) give examples showing the insufficiencies of such properties.

To give a sense of the insufficiency of simple properties, consider the following “inclusion-exclusion”-style properties, some of which are taken from (Walley, 1991). To simplify the statement of these properties, let $\mathcal{P}^{-1} = \mathcal{P}^*$ and $\mathcal{P}^{+1} = \mathcal{P}_*$.

- (1) $\mathcal{P}^*(A_1 \cup \dots \cup A_n) \leq \sum_{i=1}^n \sum_{|I|=i} (-1)^{i+1} \mathcal{P}^{(-1)^i}(\bigcap_{j \in I} A_j)$,
- (2) $\mathcal{P}_*(A_1 \cup \dots \cup A_n) \geq \sum_{i=1}^n \sum_{|I|=i} (-1)^{i+1} \mathcal{P}^{(-1)^{i+1}}(\bigcap_{j \in I} A_j)$,
- (3) $\mathcal{P}_*(A \cup B) + \mathcal{P}_*(A \cap B) \leq \mathcal{P}_*(A) + \mathcal{P}^*(B) \leq \mathcal{P}^*(A \cup B) + \mathcal{P}^*(A \cap B)$,

3. In the literature, the term upper probability is sometimes used in a more restricted sense than here. For example, Dempster (1967) uses the term to denote a class of measures which were later characterized as Dempster-Shafer belief functions (Shafer, 1976); belief functions are in fact upper probability measures in our sense, but the converse is not true (Kyburg, 1987). In the measure theory literature, what we call upper probability measures are a special case of *upper envelopes* of measures, which are defined as the sup of sets of general measures, not just probability measures.

4. It is possible to define a notion of upper probability over an arbitrary set of subsets of Ω , not necessarily an algebra, by simply requiring that f coincides with \mathcal{P}^* on its domain, for some set \mathcal{P} of probability measures. See Walley (1991) for details.

$$(4) \mathcal{P}_*(A) + \mathcal{P}_*(B) \leq \mathcal{P}_*(A \cup B) + \mathcal{P}^*(A \cap B) \leq \mathcal{P}^*(A) + \mathcal{P}^*(B),$$

$$(5) \mathcal{P}_*(A) + \mathcal{P}_*(B) \leq \mathcal{P}_*(A \cap B) + \mathcal{P}^*(A \cup B) \leq \mathcal{P}^*(A) + \mathcal{P}^*(B).$$

Note that without the alternation between upper probabilities and lower probabilities, (1) and (2) would just be the standard notions of subadditivity and superadditivity, respectively. While subadditivity and superadditivity hold for upper and lower probabilities, respectively, (1) and (2) are stronger properties. It is easily verified that all five properties hold for upper probability measures. The question is whether they completely characterize the class of upper probability measures. We show the inherent incompleteness of these properties by proving that they are all derivable from the following simple property, which is by itself insufficient to characterize upper probability measures:

$$(6) \text{ If } A \cap B = \emptyset, \text{ then } \mathcal{P}^*(A) + \mathcal{P}_*(B) \leq \mathcal{P}^*(A \cup B) \leq \mathcal{P}^*(A) + \mathcal{P}^*(B).$$

Proposition 2.1: *Property (6) implies properties (1)-(5).*

Observe that our property (6) is already given by Walley (1991, p. 84), as properties (d) and (e). The following example shows the insufficiency of Property (6). Let \mathcal{P} be the set of probability measures $\{\mu_1, \mu_2, \mu_3, \mu_4\}$ over $\Omega = \{a, b, c, d\}$ (with Σ containing all subsets of Ω) defined on singletons by

$$\begin{aligned} \mu_1(a) &= \frac{1}{4} & \mu_1(b) &= \frac{1}{4} & \mu_1(c) &= \frac{1}{4} & \mu_1(d) &= \frac{1}{4} \\ \mu_2(a) &= 0 & \mu_2(b) &= \frac{1}{8} & \mu_2(c) &= \frac{3}{8} & \mu_2(d) &= \frac{1}{2} \\ \mu_3(a) &= \frac{1}{8} & \mu_3(b) &= \frac{3}{8} & \mu_3(c) &= 0 & \mu_3(d) &= \frac{1}{2} \\ \mu_4(a) &= \frac{3}{8} & \mu_4(b) &= 0 & \mu_4(c) &= \frac{1}{8} & \mu_4(d) &= \frac{1}{2}, \end{aligned}$$

and extended by additivity to all of Σ . This defines an upper probability measure \mathcal{P}^* over Σ . Consider the function $v_\epsilon : \Sigma \rightarrow [0, 1]$ defined by

$$v_\epsilon(X) = \begin{cases} \mathcal{P}^*(X) + \epsilon & \text{if } X = \{a, b, c\} \\ \mathcal{P}^*(X) & \text{otherwise.} \end{cases}$$

We claim that the function v_ϵ , for small enough $\epsilon > 0$, satisfies property (6), but cannot be an upper probability measure.

Proposition 2.2: *For $0 < \epsilon < \frac{1}{8}$, the function v_ϵ satisfies property (6), but is not an upper probability measure. That is, we cannot find a set \mathcal{P}' of probability measures such that $v_\epsilon = (\mathcal{P}')^*$.*

This example clearly illustrates the need to go beyond the inclusion-exclusion principle to find properties that characterize upper probability measures. As it turns out, various complete characterizations have been described in the literature (Lorentz, 1952; Huber, 1976, 1981; Williams, 1976; Wolf, 1977; Giles, 1982; Anger & Lembcke, 1985; Walley, 1991). Most of these characterizations are obtained by considering upper and lower *expectations*, rather than working directly with upper and lower probabilities. Anger and Lembcke (1985)

give a characterization in terms of upper and lower probabilities. Since their characterization is particularly well-suited to the logic presented in the next section, we review it here.

The characterization is based on the notion of *set cover*. A set A is said to be *covered* n times by a multiset $\{\{A_1, \dots, A_m\}\}$ of sets if every element of A appears in at least n sets from A_1, \dots, A_m : for all $x \in A$, there exists distinct i_1, \dots, i_n in $\{1, \dots, m\}$ such that for all $j \leq n$, $x \in A_{i_j}$. It is important to note here that $\{\{A_1, \dots, A_m\}\}$ is a multiset, not a set; the A_i 's are not necessarily distinct. (We use the $\{\{\}\}$ notation to denote multisets.) An (n, k) -cover of (A, Ω) is a multiset $\{\{A_1, \dots, A_m\}\}$ that covers Ω k times and covers A $n + k$ times. For example, $\{\{1, 2\}, \{2, 3\}, \{1, 3\}\}$ covers $\{1, 2, 3\}$ 2 times, and $\{\{\{1, 2\}, \{2, 3\}, \{1, 3\}, \{2\}, \{2\}\}\}$ is a $(2, 2)$ cover of $(\{2\}, \{1, 2, 3\})$.

The notion of (n, k) -cover is the key concept in Anger and Lembcke's characterization of upper probability measures.

Theorem 2.3: (Anger & Lembcke, 1985) *Suppose that Ω is a set, Σ is an algebra of subsets of Ω , and $v : \Sigma \rightarrow \mathbb{R}$. Then there exists a set \mathcal{P} of probability measures with $v = \mathcal{P}^*$ if and only if v satisfies the following three properties:*

- UP1. $v(\emptyset) = 0$,
- UP2. $v(\Omega) = 1$,
- UP3. *for all natural numbers m, n, k and all subsets A_1, \dots, A_m in Σ , if $\{\{A_1, \dots, A_m\}\}$ is an (n, k) -cover of (A, Ω) , then $k + nv(A) \leq \sum_{i=1}^m v(A_i)$.*

Proof: We reproduce a proof of this result in Appendix B. ■

Note that **UP1** is redundant in the presence of **UP2** and **UP3**. Indeed, $\{\{\Omega, \emptyset\}\}$ is a $(0, 1)$ -cover of (Ω, Ω) , and applying **UP3** yields $v(\emptyset) + v(\Omega) = 1$. Since **UP2** states that $v(\Omega) = 1$, this means that $v(\emptyset) = 0$. A further consequence of **UP3** is that if $A \subseteq B$, then $v(A) \leq v(B)$, since $\{\{B\}\}$ is a $(1, 0)$ -cover of (A, Ω) . Therefore, for all $A \in \Sigma$, $v(A) \in [0, 1]$.

We need to strengthen Theorem 2.3 in order to prove the main result of this paper, namely, the completeness of the axiomatization of the logic we introduce in the next section. We show that if the cardinality of the state space Ω is finite, then we need only finitely many instances of property **UP3**. Notice that we cannot derive this from Theorem 2.3 alone: even if $|\Omega|$ is finite, **UP3** does not provide any bound on m , the number of sets to consider in an (n, k) cover of a set A . Indeed, there does not seem to be any *a priori* reason why the value of m , n , and k can be bounded. Bounding this value of m (and hence of n and k , since they are no larger than m) is one of the key technical results of this paper, and a necessary foundation for our work.

Theorem 2.4: *There exist constants B_0, B_1, \dots such that if Ω is a finite set, Σ is an algebra of subsets of Ω , and $v : \Sigma \rightarrow \mathbb{R}$, then there exists a set \mathcal{P} of probability measures such that $v = \mathcal{P}^*$ if and only if v satisfies the following properties:*

- UPF1. $v(\emptyset) = 0$,
- UPF2. $v(\Omega) = 1$,
- UPF3. *for all integers $m, n, k \leq B_{|\Omega|}$ and all sets A_1, \dots, A_m , if $\{\{A_1, \dots, A_m\}\}$ is an (n, k) -cover of (A, Ω) , then $k + nv(A) \leq \sum_{i=1}^m v(A_i)$.*

Property **UPF3** is significantly weaker than **UP3**. In principle, checking that **UP3** holds for a given function requires checking that it holds for arbitrarily large collections of sets, even if the underlying set Ω is finite. On the other hand, **UPF3** guarantees that if Ω is finite, then it is in fact sufficient to look at collections of size at most $B_{|\Omega|}$. This observation is key to the completeness result.

Theorem 2.4 does not prescribe any values for the constants B_0, B_1, \dots . Indeed, the proof found in Appendix A relies on a Ramsey-theoretic argument that does not even provide a bound on the B_i 's. We could certainly attempt to obtain such bounds, but obtaining them is completely unnecessary for our purposes. To get completeness of the axiomatization of the logic introduced in the next section, it is sufficient for there to exist finite constants B_0, B_1, \dots .

3. The Logic

The syntax for the logic is straightforward, and is taken from FHM. We fix a set $\Phi_0 = \{p_1, p_2, \dots\}$ of *primitive propositions*. The set Φ of *propositional formulas* is the closure of Φ_0 under \wedge and \neg . We assume a special propositional formula *true*, and abbreviate \neg *true* as *false*. We use p to represent primitive propositions, and φ and ψ to represent propositional formulas. A *term* is an expression of the form $\theta_1 l(\varphi_1) + \dots + \theta_k l(\varphi_k)$, where $\theta_1, \dots, \theta_k$ are reals and $k \geq 1$. A *basic likelihood formula* is a statement of the form $t \geq \alpha$, where t is a term and α is a real. A *likelihood formula* is a Boolean combination of basic likelihood formulas. We use f and g to represent likelihood formulas. We use obvious abbreviations where needed, such as $l(\varphi) - l(\psi) \geq a$ for $l(\varphi) + (-1)l(\psi) \geq a$, $l(\varphi) \geq l(\psi)$ for $l(\varphi) - l(\psi) \geq 0$, $l(\varphi) \leq a$ for $-l(\varphi) \geq -a$, $l(\varphi) < a$ for $\neg(l(\varphi) \geq a)$ and $l(\varphi) = a$ for $(l(\varphi) \geq a) \wedge (l(\varphi) \leq a)$. Define the length $|f|$ of the likelihood formula f to be the number of symbols required to write f , where each coefficient is counted as one symbol. Let \mathcal{L}^{QU} be the language consisting of likelihood formulas. (The QU stands for *quantitative uncertainty*. The name for the logic is taken from (Halpern, 2002).)

In FHM, the operator l was interpreted as either “probability” or “belief” (in the sense of Dempster-Shafer). Under the first interpretation, a formula such as $l(\varphi) + l(\psi) \geq 2/3$ would be interpreted as “the probability of φ plus the probability of ψ is at least $2/3$ ”. Here we interpret l as upper probability. Thus, the logic allows us to make statements about inequalities involving upper probabilities.

To capture this interpretation, we assign a semantics to formulas in \mathcal{L}^{QU} using an upper probability space, as defined in Section 2. Formally, an *upper probability structure* is a tuple $M = (\Omega, \Sigma, \mathcal{P}, \pi)$ where $(\Omega, \Sigma, \mathcal{P})$ is an upper probability space and π associates with each state (or world) in Ω a truth assignment on the primitive propositions in Φ_0 . Thus, $\pi(s)(p) \in \{\mathbf{true}, \mathbf{false}\}$ for $s \in \Omega$ and $p \in \Phi_0$. Let $\llbracket p \rrbracket_M = \{s \in \Omega : \pi(s)(p) = \mathbf{true}\}$. We call M *measurable* if for each $p \in \Phi_0$, $\llbracket p \rrbracket_M$ is measurable. If M is measurable then $\llbracket \varphi \rrbracket_M$ is measurable for all propositional formulas φ . In this paper, we restrict our attention to measurable upper probability structures. Extend $\pi(s)$ to a truth assignment on all propositional formulas in a standard way, and associate with each propositional formula the set $\llbracket \varphi \rrbracket_M = \{s \in \Omega : \pi(s)(\varphi) = \mathbf{true}\}$. An easy structural induction shows that $\llbracket \varphi \rrbracket_M$

is a measurable set. If $M = (\Omega, \Sigma, \mathcal{P}, \pi)$, let

$$\begin{aligned} M \models \theta_1 l(\varphi_1) + \cdots + \theta_k l(\varphi_k) \geq \alpha &\text{ iff } \theta_1 \mathcal{P}^*(\llbracket \varphi_1 \rrbracket_M) + \cdots + \theta_k \mathcal{P}^*(\llbracket \varphi_k \rrbracket_M) \geq \alpha \\ M \models \neg f &\text{ iff } M \not\models f \\ M \models f \wedge g &\text{ iff } M \models f \text{ and } M \models g. \end{aligned}$$

Note that \mathcal{L}^{QU} can express lower probabilities: it follows from the duality between upper and lower probabilities that $M \models -l(\neg\varphi) \geq \beta - 1$ iff $\mathcal{P}_*(\llbracket \neg\varphi \rrbracket_M) \geq \beta$.⁵

Consider the following axiomatization \mathbf{AX}^{up} of upper probability, which we prove sound and complete in the next section. The key axioms are simply a translation into \mathcal{L}^{QU} of the characterization of upper probability given in Theorem 2.3. As in FHM, \mathbf{AX}^{up} is divided into three parts, dealing respectively with propositional reasoning, reasoning about linear inequalities, and reasoning about upper probabilities.

Propositional reasoning

Taut. All instances of propositional tautologies in \mathcal{L}^{QU} (see below).

MP. From f and $f \implies g$ infer g .

Reasoning about linear inequalities

Ineq. All instances of valid formulas about linear inequalities (see below).

Reasoning about upper probabilities

L1. $l(\text{false}) = 0$.

L2. $l(\text{true}) = 1$.

L3. $l(\varphi) \geq 0$.

L4. $l(\varphi_1) + \cdots + l(\varphi_m) - nl(\varphi) \geq k$ if $\varphi \implies \bigvee_{J \subseteq \{1, \dots, m\}, |J|=k+n} \bigwedge_{j \in J} \varphi_j$ and $\bigvee_{J \subseteq \{1, \dots, m\}, |J|=k} \bigwedge_{j \in J} \varphi_j$ are propositional tautologies.⁶

L5. $l(\varphi) = l(\psi)$ if $\varphi \Leftrightarrow \psi$ is a propositional tautology.

The only difference between \mathbf{AX}^{up} and the axiomatization for reasoning about probability given in FHM is that the axiom $l(\varphi \wedge \psi) + l(\varphi \wedge \neg\psi) = l(\varphi)$ in FHM, which expresses the additivity of probability, is replaced by **L4**. Although it may not be immediately obvious, **L4** is the logical analogue of **UP3**. To see this, first note that $\{A_1, \dots, A_m\}$ covers A m times if and only if $A \subseteq \bigcup_{J \subseteq \{1, \dots, m\}, |J|=n} \bigcap_{j \in J} A_j$. Thus, the formula $\varphi \implies \bigvee_{J \subseteq \{1, \dots, m\}, |J|=k+n} \bigwedge_{j \in J} \varphi_j$ says that φ (more precisely, the set of worlds where φ is true) is covered $k+n$ times by $\{\{\varphi_1, \dots, \varphi_n\}\}$, while $\bigvee_{J \subseteq \{1, \dots, m\}, |J|=k} \bigwedge_{j \in J} \varphi_j$ says that the whole space is covered k times by $\{\{\varphi_1, \dots, \varphi_n\}\}$; roughly speaking, the multiset $\{\{\varphi_1, \dots, \varphi_n\}\}$ is an (n, k) -cover of (φ, true) . The conclusion of **L4** thus corresponds to the conclusion of

5. Another approach, more in keeping with FHM, would be to interpret l as a lower probability measure. On the other hand, interpreting l as an upper probability measure is more in keeping with the literature on upper probabilities.

6. Note that, according to the syntax of \mathcal{L}^{QU} , $\varphi_1, \dots, \varphi_m$ must be propositional formulas.

UP3. Note that in the same way that **UP1** follows from **UP2** and **UP3**, axiom **L1** (as well as **L3**) follows from **L2** and **L4**.

Instances of **Taut** include all formulas of the form $f \vee \neg f$, where f is an arbitrary formula in \mathcal{L}^{QU} . We could replace **Taut** by a simple collection of axioms that characterize propositional reasoning (see, for example, (Mendelson, 1964)), but we have chosen to focus on aspects of reasoning about upper probability.

As in FHM, the axiom **Ineq** includes “all valid formulas about linear inequalities.” An *inequality formula* is a formula of the form $a_1x_1 + \dots + a_nx_n \geq c$, over variables x_1, \dots, x_n . An inequality formula is said to *valid* if it is true under every possible assignment of real numbers to variables. To get an instance of **Ineq**, we replace each variable x_i that occurs in a valid inequality formula by a primitive likelihood term of the form $l(\varphi_i)$ (naturally each occurrence of the variable x_i must be replaced by the same primitive likelihood term $l(\varphi_i)$). As with **Taut**, we can replace **Ineq** by a sound and complete axiomatization for Boolean combinations of linear inequalities. One such axiomatization is given in FHM.

4. Soundness and Completeness

A formula f is *provable in an axiom system AX* if f can be proven using the axioms and rules of inferences of **AX**. **AX** is *sound* with respect to a class \mathcal{M} of structures if every formula provable in **AX** is valid in \mathcal{M} (i.e., valid in every structure in \mathcal{M}); **AX** is *complete* with respect to \mathcal{M} if every formula valid in \mathcal{M} is provable in **AX**.

Our goal is to prove that **AX^{up}** is a sound and complete axiomatization for reasoning about upper probability (i.e., with respect to upper probability structures). The soundness of **AX^{up}** is immediate from our earlier discussion. Completeness is, as usual, harder. Unfortunately, the standard technique for proving completeness in modal logic, which involves considering maximal consistent sets and canonical structures (see, for example, (Popkorn, 1994)) does not work. We briefly review the approach, just to point out the difficulties.

The standard approach uses the following definitions. A formula σ is *consistent* with an axiom system **AX** if $\neg\sigma$ is not provable from **AX**. A finite set of formulas $\{\sigma_1, \dots, \sigma_n\}$ is consistent with **AX** if the formula $\sigma_1 \wedge \dots \wedge \sigma_n$ is consistent with **AX**; an infinite set of formulas is consistent with **AX** if all its finite subsets are consistent with **AX**. F is a *maximal AX-consistent set* if F is consistent with **AX** and no strict superset of F is consistent with **AX**. If **AX** includes **Taut** and **MP**, then it is not hard to show, using only propositional reasoning, that every **AX**-consistent set of formulas can be extended to a maximal **AX**-consistent set.

To show that **AX** is complete with respect to some class \mathcal{M} of structures, we must show that every formula that is valid in \mathcal{M} is provable in **AX**. To do this, it is sufficient to show that every **AX**-consistent formula is satisfiable in some structure in \mathcal{M} . Typically, this is done by constructing what is called a *canonical structure* M^c in \mathcal{M} whose states are the maximal **AX**-consistent sets, and then showing that a formula σ is satisfied in a world w in M^c iff σ is one of the formulas in the canonical set associated with world w .

Unfortunately, this approach cannot be used to prove completeness here. To see this, consider the set of formulas

$$F' = \{l(\varphi) \leq \frac{1}{n}, n = 1, 2, \dots\} \cup \{l(\varphi) > 0\}.$$

This set is clearly \mathbf{AX}^{up} -consistent according to our definition, since every finite subset is satisfiable in an upper probability structure and \mathbf{AX}^{up} is sound with respect to upper probability structures. It thus can be extended to a maximal \mathbf{AX}^{up} -consistent set F . However, the set F' of formulas is not satisfiable: it is not possible to assign $l(\varphi)$ a value that will satisfy all the formulas at the same time. Hence, F is not satisfiable. Thus, the canonical model approach, at least applied naively, simply will not work.

We take a different approach here, similar to the one taken in FHM. We do not try to construct a single canonical model. Of course, we still must show that if a formula f is \mathbf{AX}^{up} -consistent then it is satisfiable in an upper probability structure. We do this by an explicit construction, depending on f . We proceed as follows.

By a simple argument, we can easily reduce the problem to the case where f is a conjunction of basic likelihood formulas and negations of basic likelihood formulas. Let p_1, \dots, p_N be the primitive propositions that appear in f . Observe that there are 2^{2^N} inequivalent propositional formulas over p_1, \dots, p_N . The argument goes as follows. Let an *atom over* p_1, \dots, p_N be a formula of the form $q_1 \wedge \dots \wedge q_N$, where q_i is either p_i or $\neg p_i$. There are clearly 2^N atoms over p_1, \dots, p_N . Moreover, it is easy to see that any formula over p_1, \dots, p_N can be written in a unique way as a disjunction of atoms. There are 2^{2^N} such disjunctions, so the claim follows.

Continuing with the construction of a structure satisfying f , let $\rho_1, \dots, \rho_{2^{2^N}}$ be some canonical listing of the inequivalent formulas over p_1, \dots, p_N . Without loss of generality, we assume that ρ_1 is equivalent to *true*, and $\rho_{2^{2^N}}$ is equivalent to *false*. Since every propositional formula over p_1, \dots, p_N is provably equivalent to some ρ , it follows that f is provably equivalent to a formula f' where each conjunct of f' is of the form $\theta_1 l(\rho_1) + \dots + \theta_{2^{2^N}} l(\rho_{2^{2^N}}) \geq \beta$. Note that the negation of such a formula has the form $\theta_1 l(\rho_1) + \dots + \theta_{2^{2^N}} l(\rho_{2^{2^N}}) < \beta$ or, equivalently, $(-\theta_1)l(\rho_1) + \dots + (-\theta_{2^{2^N}})l(\rho_{2^{2^N}}) > -\beta$. Thus, the formula f gives rise in a natural way to a system of inequalities of the form:

$$\begin{aligned}
 \theta_{1,1}l(\rho_1) + \dots + \theta_{1,2^{2^N}}l(\rho_{2^{2^N}}) &\geq \alpha_1 \\
 \vdots &\vdots \\
 \theta_{r,1}l(\rho_1) + \dots + \theta_{r,2^{2^N}}l(\rho_{2^{2^N}}) &\geq \alpha_r \\
 \theta'_{1,1}l(\rho_1) + \dots + \theta'_{1,2^{2^N}}l(\rho_{2^{2^N}}) &> \beta_1 \\
 \vdots &\vdots \\
 \theta'_{s,1}l(\rho_1) + \dots + \theta'_{s,2^{2^N}}l(\rho_{2^{2^N}}) &> \beta_s.
 \end{aligned} \tag{1}$$

We can express (1) as a conjunction of inequality formulas, by replacing each occurrence of $l(\rho_i)$ in (1) by x_i . Call this inequality formula \bar{f} .

If f is satisfiable in some upper probability structure M , then we can take x_i to be the upper probability of ρ_i in M ; this gives a solution of \bar{f} . However, \bar{f} may have a solution without f being satisfiable. For example, if f is the formula $l(p) = 1/2 \wedge l(\neg p) = 0$, then \bar{f} has an obvious solution; f , however, is not satisfiable in an upper probability structure, because the upper probability of the set corresponding to p and the upper probability of the set corresponding to $\neg p$ must sum to at least 1 in all upper probability structures. Thus, we must add further constraints to the solution to force it to act like an upper probability.

UP1-UP3 or, equivalently, the axioms **L1-L4**, describe exactly what additional constraints are needed. The constraint corresponding to **L1** (or **UP1**) is just $x_1 = 0$, since

we have assumed ρ_1 is the formula *false*. Similarly, the constraint corresponding to **L2** is $x_{2^{2N}} = 1$. The constraint corresponding to **L3** is $x_i \geq 0$, for $i = 1, \dots, 2^{2N}$. What about **L4**? This seems to require an infinite collection of constraints, just as **UP3** does.⁷

This is where **UPF3** comes into play. It turns out that, if f is satisfiable at all, it is satisfiable in a structure with at most 2^N worlds, one for each atom over p_1, \dots, p_N . Thus, we need to add only instances of **L4** where $k, m, n < B_{2N}$ and $\varphi_1, \dots, \varphi_m, \varphi$ are all among $\rho_1, \dots, \rho_{2^{2N}}$. Although this is a large number of formulas (in fact, we do not know exactly how large, since it depends on B_{2N} , which we have not computed), it suffices for our purposes that it is a finite number. For each of these instances of **L4**, there is an inequality of the form $a_1 x_1 + \dots + a_{2^{2N}} x_{2^{2N}} \geq k$. Let \hat{f} , the *inequality formula corresponding to f* , be the conjunction consisting of \bar{f} , together with all the inequalities corresponding to the relevant instances of **L4**, and the equations and inequalities $x_1 = 0$, $x_{2^{2N}} = 1$, and $x_i \geq 0$ for $i = 1, \dots, 2^{2N}$, corresponding to axioms **L1–L3**.

Proposition 4.1: *The formula f is satisfiable in an upper probability structure iff the inequality formula \hat{f} has a solution. Moreover, if \hat{f} has a solution, then f is satisfiable in an upper probability structure with at most $2^{|\hat{f}|}$ worlds.*

Theorem 4.2: *The axiom system \mathbf{AX}^{up} is sound and complete for upper probability structures.*

Proof: For soundness, it is easy to see that every axiom is valid for upper probability structures, including **L4**, which represents **UP3**.

For completeness, we proceed as in the discussion above. Assume that formula f is not satisfiable in an upper probability structure; we must show that f is \mathbf{AX}^{up} -inconsistent. We first reduce f to a canonical form. Let $g_1 \vee \dots \vee g_r$ be a disjunctive normal form expression for f (where each g_i is a conjunction of basic likelihood formulas and their negations). Using propositional reasoning, we can show that f is provably equivalent to this disjunction. Since f is unsatisfiable, each g_i must also be unsatisfiable. Thus, it is sufficient to show that any unsatisfiable conjunction of basic likelihood formulas and their negations is inconsistent. Assume that f is such a conjunction. Using propositional reasoning and axiom **L5**, f is equivalent to a likelihood formula f' that refers to 2^{2N} propositional formulas, say $\rho_1, \dots, \rho_{2^{2N}}$. Since f is unsatisfiable, so is f' . By Proposition 4.1, the inequality formula \hat{f}' corresponding to f' has no solution. Thus, by **Ineq**, the formula $\neg f''$ that results by replacing each instance of x_i in \hat{f}' by $l(\rho_i)$ is \mathbf{AX}^{up} -provable. All the conjuncts of f'' that are instances of axioms **L1–L4** are \mathbf{AX}^{up} -provable. It follows that $\neg f'$ is \mathbf{AX}^{up} -provable, and hence so is $\neg f$. ■

5. Decision Procedure

Having settled the issue of the soundness and completeness of the axiom system \mathbf{AX}^{up} , we turn to the problem of the complexity of deciding satisfiability. Recall the problem of

7. Although we are dealing with only finitely many formulas here, $\rho_1, \dots, \rho_{2^{2N}}$, recall that the formulas $\varphi_1, \dots, \varphi_m$ in **L4** need not be distinct, so there are potentially infinitely many instances of **L4** to deal with.

satisfiability: given a likelihood formula f , we want to determine if there exists an upper probability structure M such that $M \models f$. As we now show, the satisfiability problem is NP-complete, and thus no harder than satisfiability for propositional logic.

For the decision problem to make sense, we need to restrict our language slightly. If we allow real numbers as coefficients in likelihood formulas, we have to carefully discuss the issue of representation of such numbers. To avoid these complications, we restrict our language (in this section) to allow only integer coefficients. Note that we can still express rational coefficients by the standard trick of “clearing the denominator”. For example, we can express $\frac{2}{3}l(\varphi) \geq 1$ by $2l(\varphi) \geq 3$ and $l(\varphi) \geq \frac{2}{3}$ by $3l(\varphi) \geq 2$. Recall that we defined $|f|$ to be the length of f , that is, the number of symbols required to write f , where each coefficient is counted as one symbol. Define $\|f\|$ to be the length of the longest coefficient appearing in f , when written in binary. The size of a rational number $\frac{a}{b}$, denoted $\|\frac{a}{b}\|$, where a and b are relatively prime, is defined to be $\|a\| + \|b\|$.

A preliminary result required for the analysis of the decision procedure shows that if a formula is satisfied in some upper probability structure, then it is satisfied in a structure $(\Omega, \Sigma, \mathcal{P}, \pi)$, which is “small” in terms of the number of states in Ω , the cardinality of the set \mathcal{P} of probability measures, and the size of the coefficients in f .

Theorem 5.1: *Suppose f is a likelihood formula that is satisfied in some upper probability structure. Then f is satisfied in a structure $(\Omega, \Sigma, \mathcal{P}, \pi)$, where $|\Omega| \leq |f|^2$, $\Sigma = 2^\Omega$ (every subset of Ω is measurable), $|\mathcal{P}| \leq |f|$, $\mu(w)$ is a rational number such that $\|\mu(w)\|$ is $O(|f|^2\|f\| + |f|^2 \log(|f|))$ for every world $w \in \Omega$ and $\mu \in \mathcal{P}$, and $\pi(w)(p) = \mathbf{false}$ for every world $w \in \Omega$ and every primitive proposition p not appearing in f .*

Theorem 5.2: *The problem of deciding whether a likelihood formula is satisfiable in an upper probability structure is NP-complete.*

Proof: For the lower bound, it is clear that a given propositional formula φ is satisfiable iff the likelihood formula $l(\varphi) > 0$ is satisfiable, therefore the satisfiability problem is NP-hard. For the upper bound, given a likelihood formula f , we guess a “small” satisfying structure $M = (\Omega, \Sigma, \mathcal{P}, \pi)$ for f of the form guaranteed to exist by Theorem 5.1. We can describe such a model M in size polynomial in $|f|$ and $\|f\|$. (The fact that $\pi(w)(p) = \mathbf{false}$ for every world $w \in \Omega$ and every primitive proposition p not appearing in f means that we must describe π only for propositions that appear in f .) We verify that $M \models f$ as follows. Let $l(\psi)$ be an arbitrary likelihood term in f . We compute $\llbracket \psi \rrbracket_M$ by checking the truth assignment of each $s \in \Omega$ and seeing whether this truth assignment makes ψ true. We then replace each occurrence of $l(\psi)$ in f by $\max_{\mu \in \mathcal{P}} \{ \sum_{s \in \llbracket \psi \rrbracket_M} \mu(s) \}$ and verify that the resulting expression is true. ■

6. Conclusion

We have considered a logic with the same syntax as the logic for reasoning about probability, inner measures, and belief presented in FHM, with uncertainty interpreted as the upper probability of a set of probability measures. Under this interpretation, we have provided a sound and complete axiomatization for the logic. We further showed that the satisfiability problem is NP-complete (as it is for reasoning about probability, inner measures, and

beliefs), despite having to deal with probability structures with possibility infinitely many states and infinite sets of probability measures. The key step in the axiomatization involves finding a characterization of upper probability measures that can be captured in the logic. The key step in the complexity result involves showing that if a formula is satisfiable at all, it is satisfiable in a “small” structure, where the size of the state space, as well as the size of the set of probability measures and the size of all probabilities involved, are polynomial in the length of the formula.

Given the similarity in spirit of the results for the various interpretations of the uncertainty operator (as a probability, inner measure, belief function, and upper probability), including the fact that the complexity of the decision problem is NP-complete in all cases, we conjecture that there is some underlying result from which all these results should follow. It would be interesting to make that precise.

In FHM, conditional probabilities as well as probabilities are investigated. We have not, in this paper, discussed conditional upper probabilities. The main reason for this is that, unlike probability, we cannot characterize conditional upper probabilities in terms of (unconditional) upper probabilities. Thus, our results really tell us nothing about conditional upper probabilities. It might be of interest to consider a logic that allows conditional upper probabilities as primitive likelihood terms (that is, allows likelihood terms of the form $l(\varphi|\psi)$). While there is no intrinsic difficulty giving semantics to such a language, it is far from clear what an appropriate axiomatization would be, or the effect of this extension on complexity.

Finally, it is worth noting that the semantic framework developed here and in FHM is in fact rich enough to talk about gambles (that is, real-valued functions over the set of states) and the expectation of such gambles. Expectation functions can be defined for the different measures of uncertainty, including upper probabilities, and it is not difficult to extend the FHM logic in order to reason about expectation. One advantage of working with expectation functions is that they are typically easier to characterize than the corresponding measures; for instance, the characterization of expected upper probabilities is much simpler than that of upper probabilities (Huber, 1981; Walley, 1981, 1991). However, getting a complete axiomatization is quite nontrivial. We refer the reader to (Halpern & Pucella, 2002) for more details on this subject. We remark that Wilson and Moral (1994) take as their starting point Walley’s notion of lower and upper previsions. They consider when acceptance of one set of gambles implies acceptance of another gamble. Since acceptance involves expectation, it cannot be expressed in the logic considered in this paper; however, it can be expressed easily in the logic of (Halpern & Pucella, 2002).

Acknowledgments

A preliminary version of this paper appears in *Uncertainty in Artificial Intelligence, Proceedings of the Seventeenth Conference*, 2001. Thanks to Dexter Kozen, Jon Kleinberg, and Hubie Chen for discussions concerning set covers. Vicky Weissman read a draft of this paper and provided numerous helpful comments. We also thank the anonymous UAI and JAIR reviewers for their useful comments and suggestions. 41, N00014-01-10-511, and N00014-01-1-0795. The first author was also supported in part by a Guggenheim and a Fulbright Fellowship while on sabbatical leave; sabbatical support from CWI and the Hebrew University of Jerusalem is also gratefully acknowledged.

Appendix A. Proofs

Proposition 2.1: *Property (6) implies properties (1)-(5).*

Proof: We introduce the following auxiliary properties to help derive the implications:

$$(7) \mathcal{P}_*(A) + \mathcal{P}_*(B) \leq \mathcal{P}_*(A \cup B) + \mathcal{P}^*(A \cap B).$$

$$(8) \mathcal{P}_*(A) + \mathcal{P}_*(B) \leq \mathcal{P}_*(A \cap B) + \mathcal{P}^*(A \cup B).$$

$$(9) \mathcal{P}_*(A \cup B) + \mathcal{P}_*(A \cap B) \leq \mathcal{P}_*(A) + \mathcal{P}^*(B).$$

(10) If $A \cap B = \emptyset$, then

$$\mathcal{P}_*(A) + \mathcal{P}_*(B) \leq \mathcal{P}_*(A \cup B) \leq \mathcal{P}_*(A) + \mathcal{P}^*(B) \leq \mathcal{P}^*(A \cup B) \leq \mathcal{P}^*(A) + \mathcal{P}^*(B).$$

Using these properties, we show the following chain of implications:

$$\begin{array}{llll} & (10) \implies (9) \implies (3) & & \\ (6) \implies (10) & (10) \implies (7) \implies (4) & (4), (5) \implies (1), (2). & \\ & (10) \implies (8) \implies (5) & & \end{array}$$

The implication (4), (5) \implies (1), (2) follows easily by mutual induction on n . The base case is the following instances of properties (4) and (5): $\mathcal{P}_*(A \cup B) \geq \mathcal{P}_*(A) + \mathcal{P}_*(B) - \mathcal{P}^*(A \cap B)$ and $\mathcal{P}^*(A \cup B) \leq \mathcal{P}^*(A) + \mathcal{P}^*(B) - \mathcal{P}_*(A \cap B)$. The details are left to the reader.

We now prove the remaining implications.

(9) \implies (3): Since (9) is already one of the inequalities in (3), it remains to show that it implies the other inequality in (3), that is, $\mathcal{P}_*(A) + \mathcal{P}^*(B) \leq \mathcal{P}^*(A \cup B) + \mathcal{P}^*(A \cap B)$.

$$\begin{aligned} \mathcal{P}^*(A \cup B) + \mathcal{P}^*(A \cap B) &= 1 - \mathcal{P}_*(\overline{A \cup B}) + 1 - \mathcal{P}_*(\overline{A \cap B}) \\ &= 1 - \mathcal{P}_*(\overline{A} \cap \overline{B}) + 1 - \mathcal{P}_*(\overline{A} \cup \overline{B}) \\ &= 2 - (\mathcal{P}_*(\overline{A} \cap \overline{B}) + \mathcal{P}_*(\overline{A} \cup \overline{B})) \\ &= 2 - (\mathcal{P}_*(\overline{B} \cap \overline{A}) + \mathcal{P}_*(\overline{B} \cup \overline{A})) \\ &\geq 2 - (\mathcal{P}_*(\overline{B}) + \mathcal{P}^*(\overline{A})) \\ &= 1 - \mathcal{P}_*(\overline{B}) + 1 - \mathcal{P}^*(\overline{A}) \\ &= \mathcal{P}^*(B) + \mathcal{P}_*(A). \end{aligned}$$

(7) \implies (4): Since (7) is already one of the inequalities in (4), it remains to show that it implies the other inequality in (4), that is, $\mathcal{P}_*(A \cup B) + \mathcal{P}^*(A \cap B) \leq \mathcal{P}^*(A) + \mathcal{P}^*(B)$.

$$\begin{aligned}
 \mathcal{P}^*(A) + \mathcal{P}^*(B) &= 1 - \mathcal{P}_*(\overline{A}) + 1 - \mathcal{P}_*(\overline{B}) \\
 &= 2 - (\mathcal{P}_*(\overline{A}) + \mathcal{P}_*(\overline{B})) \\
 &\geq 2 - (\mathcal{P}_*(\overline{A \cup B}) + \mathcal{P}^*(\overline{A \cap B})) \\
 &= 1 - \mathcal{P}_*(\overline{A \cup B}) + 1 - \mathcal{P}^*(\overline{A \cap B}) \\
 &= 1 - \mathcal{P}_*(\overline{A \cap B}) + 1 - \mathcal{P}^*(\overline{A \cup B}) \\
 &= \mathcal{P}^*(A \cap B) + \mathcal{P}_*(A \cup B).
 \end{aligned}$$

(8) \implies (5): Since (8) is already one of the inequalities in (5), it remains to show that it implies the other inequality in (5), that is, $\mathcal{P}_*(A \cap B) + \mathcal{P}^*(A \cup B) \leq \mathcal{P}^*(A) + \mathcal{P}^*(B)$.

$$\begin{aligned}
 \mathcal{P}^*(A) + \mathcal{P}^*(B) &= 1 - \mathcal{P}_*(\overline{A}) + 1 - \mathcal{P}_*(\overline{B}) \\
 &= 2 - (\mathcal{P}_*(\overline{A}) + \mathcal{P}_*(\overline{B})) \\
 &\geq 2 - (\mathcal{P}_*(\overline{A \cap B}) + \mathcal{P}^*(\overline{A \cup B})) \\
 &= 1 - \mathcal{P}_*(\overline{A \cap B}) + 1 - \mathcal{P}^*(\overline{A \cup B}) \\
 &= 1 - \mathcal{P}_*(\overline{A \cup B}) + 1 - \mathcal{P}^*(\overline{A \cap B}) \\
 &= \mathcal{P}^*(A \cup B) + \mathcal{P}_*(A \cap B).
 \end{aligned}$$

For the next implications, given A, B , let $Z = A \cap B$.

(10) \implies (9):

$$\begin{aligned}
 \mathcal{P}_*(A \cup B) &= \mathcal{P}_*((A - Z) \cup B) \\
 &\leq \mathcal{P}_*(A - Z) + \mathcal{P}^*(B) \quad [\text{since } (A - Z) \cap B = \emptyset] \\
 &\leq \mathcal{P}_*((A - Z) \cup Z) - \mathcal{P}_*(Z) + \mathcal{P}^*(B) \\
 &= \mathcal{P}_*(A) + \mathcal{P}^*(B) - \mathcal{P}_*(A \cap B).
 \end{aligned}$$

(10) \implies (7):

$$\begin{aligned}
 \mathcal{P}_*(A \cup B) &= \mathcal{P}_*((A - Z) \cup B) \\
 &\geq \mathcal{P}_*(A - Z) + \mathcal{P}_*(B) \\
 &\geq \mathcal{P}_*((A - Z) \cup Z) - \mathcal{P}^*(Z) + \mathcal{P}_*(B) \\
 &= \mathcal{P}_*(A) + \mathcal{P}_*(B) - \mathcal{P}^*(A \cap B).
 \end{aligned}$$

(10) \implies (8):

$$\begin{aligned}
 \mathcal{P}^*(A \cup B) &= \mathcal{P}^*((A - Z) \cup B) \\
 &\geq \mathcal{P}^*(A - Z) + \mathcal{P}_*(B) \\
 &\geq \mathcal{P}_*((A - Z) \cup Z) - \mathcal{P}_*(Z) + \mathcal{P}_*(B) \\
 &= \mathcal{P}_*(A) + \mathcal{P}_*(B) - \mathcal{P}_*(A \cap B).
 \end{aligned}$$

(6) \implies (10): Again, since (6) already comprises two of the inequalities in (10), it remains to show that it implies the other two, that is, if $A \cap B = \emptyset$, then

$$\mathcal{P}_*(A) + \mathcal{P}_*(B) \leq \mathcal{P}_*(A \cup B) \leq \mathcal{P}^*(A) + \mathcal{P}^*(B).$$

First, we show that $\mathcal{P}_*(A) + \mathcal{P}_*(B) \leq \mathcal{P}_*(A \cup B)$. Using (6), we know that

$$\mathcal{P}^*(\overline{A \cap B}) + \mathcal{P}_*(A) \leq \mathcal{P}^*((\overline{A \cap B}) \cup A) = \mathcal{P}^*(\overline{B}).$$

In other words, $\mathcal{P}^*(\overline{A \cap B}) \leq \mathcal{P}^*(\overline{B}) + \mathcal{P}_*(A)$. From this, we derive that

$$\begin{aligned} \mathcal{P}_*(A \cup B) &= 1 - \mathcal{P}^*(\overline{A \cup B}) \\ &= 1 - \mathcal{P}^*(\overline{A \cap B}) \\ &\geq 1 - (\mathcal{P}^*(\overline{B}) + \mathcal{P}_*(A)) \\ &= 1 - \mathcal{P}^*(\overline{B}) + \mathcal{P}_*(A) \\ &= \mathcal{P}_*(B) + \mathcal{P}_*(A). \end{aligned}$$

Second, we show that $\mathcal{P}_*(A \cup B) \leq \mathcal{P}^*(A) + \mathcal{P}_*(B)$. Using (6), we know that

$$\mathcal{P}^*(\overline{A \cap B}) + \mathcal{P}^*(A) \geq \mathcal{P}^*((\overline{A \cap B}) \cup A) = \mathcal{P}^*(\overline{B}).$$

(The last equality follows from the fact that $(\overline{A \cap B}) \cup A = \overline{B}$ when $A \cap B = \emptyset$.) In other words, $\mathcal{P}^*(\overline{A \cap B}) \geq \mathcal{P}^*(\overline{B}) - \mathcal{P}^*(A)$. From this, we derive that

$$\begin{aligned} \mathcal{P}_*(A \cup B) &= 1 - \mathcal{P}^*(\overline{A \cup B}) \\ &= 1 - \mathcal{P}^*(\overline{A \cap B}) \\ &\leq 1 - (\mathcal{P}^*(\overline{B}) - \mathcal{P}^*(A)) \\ &= 1 - \mathcal{P}^*(\overline{B}) + \mathcal{P}^*(A) \\ &= \mathcal{P}_*(B) + \mathcal{P}^*(A). \quad \blacksquare \end{aligned}$$

Proposition 2.2: For $0 < \epsilon < \frac{1}{8}$, the function v_ϵ satisfies property (6), but is not an upper probability measure. That is, we cannot find a set \mathcal{P}' of probability measures such that $v_\epsilon = (\mathcal{P}')^*$.

Proof: We are given $0 < \epsilon < \frac{1}{8}$. It is easy to check mechanically that v_ϵ satisfies (6).

We now show that there is no set \mathcal{P}' such that $v_\epsilon = (\mathcal{P}')^*$. By way of contradiction, assume there is such a \mathcal{P}' . By the properties of sup, this means that there is a $\mu \in \mathcal{P}'$ such that $\mu(\{a, b, c\}) > \frac{3}{4}$, since $v_\epsilon(\{a, b, c\}) = \frac{3}{4} + \epsilon > \frac{3}{4}$. Consider this μ in detail. Since $\mu \in \mathcal{P}$, we must have for all $X \in \Sigma$, $X \neq \{a, b, c\}$, that $\mu(X) \leq (\mathcal{P}')^*(X) = \mathcal{P}^*(X)$. In particular, $\mu(\{a, b\}), \mu(\{b, c\}), \mu(\{a, c\}) \leq \frac{1}{2}$. Therefore,

$$\mu(\{a, b\}) + \mu(\{b, c\}) + \mu(\{a, c\}) \leq \frac{3}{2}. \quad (2)$$

However, from standard properties of probability, it follows that

$$\mu(\{a, b\}) + \mu(\{b, c\}) + \mu(\{a, c\}) = 2\mu(\{a, b, c\}) > 2 \times \frac{3}{4} = \frac{3}{2},$$

which contradicts (2). Therefore, μ , and therefore \mathcal{P}' cannot exist, and v_ϵ is not an upper probability measure. ■

Theorem 2.4: *There exists constants B_0, B_1, \dots such that if Σ is an algebra of subsets of Ω and v is a function $v : \Sigma \rightarrow \mathbb{R}$, then there exists a set \mathcal{P} of probability measures such that $v = \mathcal{P}^*$ if and only if v satisfies the following properties:*

UPF1. $v(\emptyset) = 0$,

UPF2. $v(\Omega) = 1$,

UPF3. *for all integers $m, n, k \leq B_{|\Omega|}$ and all sets A_1, \dots, A_m , if $\{A_1, \dots, A_m\}$ is an (n, k) -cover of (A, Ω) , then $k + nv(A) \leq \sum_{i=1}^m v(A_i)$.*

Proof: In view of Theorem 2.3, we need only show that there exist constant B_0, B_1, \dots such that a function v satisfies **UP3** iff it satisfies **UPF3**. Clearly, **UP3** always implies **UPF3**, so it is sufficient to show that there exists B_0, B_1, \dots such that **UPF3** implies **UP3**.

We need some terminology before proceeding. An *exact (n, k) -cover* of (A, Ω) is a cover C of A with the property that every element of A appears in exactly $n + k$ sets in C , and every element of $\Omega - A$ appears in exactly k sets in C . Thus, while an (n, k) -cover of (A, Ω) can have many extra sets, as long as the sets cover A at least $n + k$ times and Ω k times, an exact cover has only the necessary sets, with the right total number of elements. An exact (n, k) -cover C of (A, Ω) is *decomposable* if there exists an exact (n_1, k_1) -cover C_1 and an exact (n_2, k_2) -cover C_2 of (A, Ω) such that C_1 and C_2 form a nontrivial partition of C , with $n = n_1 + n_2$ and $k = k_1 + k_2$. Intuitively, an exact cover C is decomposable if it can be split into two exact covers. It follows easily by induction that for any exact (n, k) -cover, there exists a (not necessarily unique) finite set of nondecomposable exact covers C_1, \dots, C_m , with C_i an exact (n_i, k_i) -cover, such that the C_i 's a nontrivial partition of C with $n = \sum_{i=1}^m n_i$ and $k = \sum_{i=1}^m k_i$. (If C is itself nondecomposable, we can take $m = 1$ and $C_1 = C$.) One can easily verify that if C is an exact (n, k) -cover of (A, Ω) and $C' \subseteq C$ is an exact (n', k') -cover of (A, Ω) with $n' + k' < n + k$, then C is decomposable.

The following lemma highlights the most important property of exact covers from our perspective. It says that for any set $A \in \Sigma$, there cannot be a “large” nondecomposable exact cover of (A, Ω) .

Lemma A.1: *There exists a sequence B'_1, B'_2, B'_3, \dots such that for all $A \subseteq \Omega$, every exact (n, k) -cover of (A, Ω) with $n > B'_{|\Omega|}$ or $k > B'_{|\Omega|}$ is decomposable.*

Proof: It is clearly sufficient to show that for any finite Ω we can find a $B_{|\Omega|}$ with the required properties. Fix a Ω . Given $A \subseteq \Omega$, we first show that there exists N_A such that if $n > N_A$ or $k > N_A$, every exact (n, k) -cover of (A, Ω) is decomposable. Suppose for the sake of contradiction that this is not the case. This means that we can find an infinite sequence C_1, C_2, \dots such that C_i is a nondecomposable exact (n_i, k_i) -cover of (A, Ω) , with either $n_1 < n_2 < \dots$ or $k_1 < k_2 < \dots$.

To derive a contradiction, we use the following lemma, known as Dickson’s Lemma (Dickson, 1913).

Lemma A.2: *Every infinite sequence of d -dimensional vectors over the natural numbers contains a monotonically nondecreasing subsequence in the pointwise ordering (where $x \leq y$ in the pointwise ordering iff $x_i \leq y_i$ for all i).*

Proof: It is straightforward to prove by induction on k that if $k \leq d$, then every infinite sequence of vectors x^1, x^2, \dots contains a subsequence x^{i_1}, x^{i_2}, \dots such that $x_j^{i_1}, x_j^{i_2}, \dots$ is a nondecreasing sequence of natural numbers for all $j \leq k$. The base case is immediate from the observation that every infinite sequence of natural numbers contains a nondecreasing subsequence. For the inductive step, observe that if x^{i_1}, x^{i_2}, \dots is a subsequence such that $x_j^{i_1}, x_j^{i_2}, \dots$ is a nondecreasing sequence of natural numbers for all $j \leq k$, then the sequence $x_{k+1}^{i_1}, x_{k+1}^{i_2}, \dots$ of natural numbers must have a nondecreasing subsequence. This determines a subsequence of the original sequence with the appropriate property for all $j \leq k + 1$. ■

Let $S_1, \dots, S_{2^{|\Omega|}}$ be an arbitrary ordering of the $2^{|\Omega|}$ subsets of Ω . We can associate with any cover C a $2^{|\Omega|}$ -dimensional vector $x^C = (x_1^C, \dots, x_{2^{|\Omega|}}^C)$, where x_i^C is the number of times the subset S_i of Ω appears in the multiset C . The key property of this association is that if C' and C are multisets, then $C' \subseteq C$ iff $x^{C'} \leq x^C$ in the pointwise ordering.

Consider the sequence of vectors x^{C_1}, x^{C_2}, \dots associated with the sequence C_1, C_2, \dots of nondecomposable exact covers of (A, Ω) . By Lemma A.2, there is a nondecreasing subsequence of vectors, $x^{C_{i_1}} \leq x^{C_{i_2}} \leq \dots$. But this means that $C_{i_1} \subseteq C_{i_2} \subseteq \dots$. Since $n_1 < n_2 < \dots$ or $k_1 < k_2 < \dots$, every cover in the chain must be distinct. But any pair of exact covers in the chain is such that $C_i \subseteq C_{i+1}$, meaning C_{i+1} is decomposable, contradicting our assumption. Therefore, there must exist an N_A such that any exact (n, k) -cover of A with $n > N_A$ or $k > N_A$ is decomposable.

Now define $B'_{|\Omega|} = \max\{N_A : A \subseteq \{1, \dots, |\Omega|\}\}$. It is easy to see that this choice works. ■

To get the constants B_1, B_2, \dots , let $B_N = 2NB'_N$, for $N = 1, 2, \dots$, where B'_N is as in Lemma A.1. We now show that **UPF3** implies **UP3** with this choice of B_1, B_2, \dots . Assume that **UPF3** holds. Fix Ω . Suppose that $C = \{A_1, \dots, A_m\}$ is an (n, k) -cover of (A, Ω) with $|C| = m$. We want to show that $k + nv(A) \leq \sum_{i=1}^m v(A_i)$. We proceed as follows.

The first step is to show that, without loss of generality, C is an exact (n, k) -cover of (A, Ω) . Let B_i consist of those states $s \in A_i$ such that either $s \in A$ and s appears in more than $n + k$ sets in A_1, \dots, A_{i-1} or $s \in \Omega - A$ and s appears in more than k sets in A_1, \dots, A_{i-1} . Let $A'_i = A_i - B_i$. Let $C' = \{A'_1, \dots, A'_m\}$. It is easy to check that C' is an exact (n, k) -cover of (A, Ω) . For if $s \in A$, then s appears in exactly $n + k$ sets in C' (it appears in A'_j iff A_j is among the first $n + k$ sets in C in which s appeared) and, similarly, if $s \in \Omega - A$, then s appears in exactly k sets in C' . Clearly if **UP3** holds for C' , then it holds for C , since $v(A'_i) \leq v(A_i)$ for $i = 1, \dots, m$. Thus, we can assume without loss of generality that C is an exact (n, k) -cover of A .

We can also assume without loss of generality that no set in C is empty (otherwise, we can simply remove the empty sets in C ; the resulting set is still an (n, k) -cover of (A, Ω)). There are now two cases to consider. If $\max(m, n, k) \leq B_{|\Omega|}$, the desired result

follows from **UPF3**. If not, consider a decomposition of C into multisets C_1, \dots, C_p , where C_h is an exact (n_h, k_h) -cover of (A, Ω) and is not further decomposable. We claim that $\max(|C_h|, n_h, k_h) \leq B_{|\Omega|}$ for $h = 1, \dots, p$. If $n_h > B_{|\Omega|}$ or $k_h > B_{|\Omega|}$, then it is immediate from Lemma A.1 that C_h can be further decomposed, contradicting the fact that C_h is not decomposable. And if $|C_h| > B_{|\Omega|}$, then observe that $\sum_{X \in C_h} |X| \geq |C_h|$. Since $|C_h| > B_{|\Omega|} = 2|\Omega|B'_{|\Omega|}$, there must be some $s \in \Omega$ which appears in at least $2B'_{|\Omega|}$ sets in C_h . Since C_h is an exact (n_h, k_h) -cover, it follows that either $n_h > B'_{|\Omega|}$ or $k_h > B'_{|\Omega|}$. But then, by Lemma A.1, C_h is decomposable, again a contradiction.

Now we can apply **UPF3** to each of C_1, \dots, C_k to get

$$\sum_{X \in C_h} v(X) - n_h v(A) \geq k_h.$$

Since the C_h 's form a decomposition of C , we have

$$\begin{aligned} & \sum_{h=1}^p \left(\sum_{X \in C_h} v(X) - n_h v(A) \right) \geq \sum_{h=1}^p k_h \\ \Rightarrow & \sum_{h=1}^p \left(\sum_{X \in C_h} v(X) \right) - \sum_{h=1}^p n_h v(A) \geq \sum_{h=1}^p k_h \\ \Rightarrow & \sum_{i=1}^m v(A_i) - \left(\sum_{h=1}^p n_h \right) v(A) \geq \sum_{h=1}^p k_h \end{aligned}$$

By decomposition, $n = \sum_{h=1}^p n_h$ and $k = \sum_{h=1}^p k_h$, and therefore $\sum_{i=1}^m v(A_i) - nv(A) \geq k$, showing that **UP3** holds, as desired. ■

Proposition 4.1: *The formula f is satisfiable in an upper probability structure iff the inequality formula \hat{f} has a solution. Moreover, if \hat{f} has a solution, then f is satisfiable in an upper probability structure with at most $2^{|f|}$ worlds.*

Proof: Assume first that f is satisfiable. Thus there is some upper probability structure $M = (\Omega, \Sigma, \mathcal{P}, \pi)$ such that $M \models f$. As in Section 4, let p_1, \dots, p_N be the primitive propositions that appear in f , and let $\rho_1, \dots, \rho_{2^{2^N}}$ be some canonical listing of the inequivalent formulas over p_1, \dots, p_N . Without loss of generality, we assume that ρ_1 is equivalent to *true*, and $\rho_{2^{2^N}}$ is equivalent to *false*. Define the vector x^* by letting $x_i^* = \mathcal{P}^*(\llbracket \rho_i \rrbracket_M)$, for $1 \leq i \leq 2^{2^N}$. Since $M \models f$, it is immediate that x^* is a solution to the inequality formula \bar{f} . Moreover, since $\rho_1 = \text{true}$ and $\rho_{2^{2^N}} = \text{false}$, it follows that $x_1^* = 0$ (since $\mathcal{P}^*(\llbracket \text{false} \rrbracket_M) = \mathcal{P}^*(\emptyset) = 0$) and $x_{2^{2^N}}^* = 1$ (since $\mathcal{P}^*(\llbracket \text{true} \rrbracket_M) = \mathcal{P}^*(\Omega) = 1$). Finally, consider a conjunct of \hat{f} corresponding to an instance of **L4**; suppose it has the form $x_{i_1} + \dots + x_{i_m} - nx_{i_{m+1}} \geq k$. Since this conjunct appears in \hat{f} , it must be the case that $(\rho_{i_{m+1}} \Rightarrow \bigvee_{J \subseteq \{1, \dots, m\}, |J|=k+n} \bigwedge_{J \subseteq \{1, \dots, m\}, j \in J} \rho_{i_j}) \wedge (\bigvee_{|J|=k} \bigwedge_{j \in J} \rho_{i_j})$ is a propositional tautology. Thus, it follows that $\llbracket \rho_{i_1} \rrbracket_M, \dots, \llbracket \rho_{i_m} \rrbracket_M$ is an (n, k) -cover for $(\llbracket \rho_{i_{m+1}} \rrbracket_M, \llbracket \text{true} \rrbracket_M)$. It follows from UP3 that

$$\mathcal{P}^*(\llbracket \rho_{i_1} \rrbracket_M) + \dots + \mathcal{P}^*(\llbracket \rho_{i_m} \rrbracket_M) - n\mathcal{P}^*(\llbracket \rho_{i_{m+1}} \rrbracket_M) \geq k.$$

Thus, x^* is a solution to the inequality formulas corresponding to **L4**. Hence, x^* is a solution to \hat{f} .

For the converse, assume that x^* is a solution to \hat{f} . We construct an upper probability structure $M = (S, E, \mathcal{P}, \pi)$ such that $M \models f$ as follows. Let p_1, \dots, p_N be the primitive propositions appearing in f . Let $S = \{\delta_1, \dots, \delta_{2^N}\}$ be the atoms over p_1, \dots, p_N . Let E be the set of all subsets of S . As observed earlier, every propositional formula over p_1, \dots, p_n is equivalent to a unique disjunction of atoms. Thus, we can get a canonical collection $\rho_1, \dots, \rho_{2^{2^N}}$ of inequivalent formulas over p_1, \dots, p_n by identifying each formula ρ_i with a different element of E , where ρ_1 corresponds to the empty set and $\rho_{2^{2^N}}$ corresponds to all of S . Define a set function v by taking $v(\{\delta_{i_1}, \dots, \delta_{i_j}\}) = x_i^*$ if ρ_i is the disjunction of the atoms $\delta_{i_1}, \dots, \delta_{i_j}$. Let $\pi(\delta)(\rho) = \mathbf{true}$ iff $\delta \Rightarrow \rho$.

It is now sufficient to show that v is an upper probability (of a set \mathcal{P} of probability measures), since then it is clear that $(S, E, \mathcal{P}, \pi) \models f$ (since x^* is a solution to \hat{f} , the system of inequalities derived from formula f). To do this, by Theorem 2.4, it suffices to verify **UPF1**, **UPF2**, and **UPF3**, using B_{2^N} in **UPF3**, since $|S| = 2^{2^N}$.

UPF1: $v(\emptyset) = x_1^* = 0$.

UPF2: $v(S) = x_{2^{2^N}}^* = 1$.

UPF3: Suppose that A and A_1, \dots, A_m are in E and satisfy the premises of property **UPF3**, with $k, m, n \leq B_{2^N}$. Let $\rho_{i_1}, \dots, \rho_{i_m}, \rho_{i_{m+1}}$ be the canonical formulas corresponding to A_1, \dots, A_m, A , respectively. Clearly, $A \subseteq \bigcup_{J \subseteq \{1, \dots, m\}, |J|=k+n} \bigcap_{j \in J} A_{i_j}$ iff $\rho_{i_{m+1}} \Rightarrow \bigvee_{J \subseteq \{1, \dots, m\}, |J|=k+n} \bigwedge_{j \in J} \rho_{i_j}$ is a propositional tautology and similarly $\Omega \subseteq \bigcup_{J \subseteq \{1, \dots, m\}, |J|=k} \bigcap_{j \in J} A_{i_j}$ iff $\bigvee_{J \subseteq \{1, \dots, m\}, |J|=k} \bigwedge_{j \in J} \rho_{i_j}$ is a propositional tautology. Thus, $\sum_{j=1}^m x_{i_j} - x_{i_{m+1}} \geq k$ is one of the inequality formulas in \hat{f} . Thus, it follows that $\sum_{j=1}^m x_{i_j}^* - x_{i_{m+1}}^* \geq k$, as desired. By our definition of v , we therefore have $k + nv(A) \leq \sum_{i=1}^m v(A_i)$, and so **UPF3** holds. ■

Theorem 5.1: *Suppose f is a likelihood formula that is satisfied in some upper probability structure. Then f is satisfied in a structure $(\Omega, \Sigma, \mathcal{P}, \pi)$, where $|\Omega| \leq |f|^2$, $\Sigma = 2^\Omega$ (every subset of Ω is measurable), $|\mathcal{P}| \leq |f|$, $\mu(w)$ is a rational number such that $\|\mu(w)\|$ is $O(|f|^2 \|f\| + |f|^2 \log(|f|))$ for every world $w \in \Omega$ and $\mu \in \mathcal{P}$, and $\pi(w)(p) = \mathbf{false}$ for every world $w \in \Omega$ and every primitive proposition p not appearing in f .*

Proof: The first step in the proof involves showing that if \mathcal{P} is a set of probability measures defined on an algebra Σ of a finite space Ω , we can assume without loss of generality that for each set $X \in \Sigma$, there is a probability measure $\mu_X \in \mathcal{P}$ such that $\mu_X(X) = \mathcal{P}^*(X)$ (rather than $\mathcal{P}^*(X)$ just being the sup of $\mu(X)$ for $\mu \in \mathcal{P}$).

Lemma A.3: *Let \mathcal{P} be a set of probability measures defined on an algebra Σ over a finite set Ω . Then there exists a set \mathcal{P}' of probability measures such that, for each $X \in \Sigma$, $\mathcal{P}^*(X) = (\mathcal{P}')^*(X)$; moreover, there is a probability measure $\mu_X \in \mathcal{P}'$ such that $\mu_X(X) = \mathcal{P}^*(X)$. In addition, for any interpretation π , if $M = (\Omega, \Sigma, \mathcal{P}, \pi)$ and $M' = (\Omega, \Sigma, \mathcal{P}', \pi)$, then for all likelihood formulas f , $M \models f$ iff $M' \models f$.*

Proof: Since Σ is finite, to show that \mathcal{P}' exists, it clearly suffices to show that, for each $X \in \Sigma$, there is a probability measure μ_X such that $\mu_X(X) = \mathcal{P}^*(X)$ and, if $\mathcal{P}' = \mathcal{P} \cup \{\mu_X\}$, then $\mathcal{P}^*(Y) = (\mathcal{P}')^*(Y)$ for all $Y \in \Sigma$.

Given X , if there exists $\mu \in \mathcal{P}$ such that $\mu(X) = \mathcal{P}^*(X)$, then we are done. Otherwise, we construct a sequence μ_1, μ_2, \dots of probability measures in \mathcal{P} such that $\lim_i \mu_i(X) = \mathcal{P}^*(X)$ and, for all $Y \in \Sigma$, the sequence $\mu_i(Y)$ converges to some limit. Let X_1, \dots, X_n be an enumeration of the sets in Σ , with $X_1 = X$. We inductively construct a sequence of measures $\mu_{m1}, \mu_{m2}, \dots$ in \mathcal{P} for $m \leq n$ such that $\mu_{mi}(X_j)$ converges to a limit for $i \leq k$ and $\lim_{i \rightarrow \infty} \mu_{mi}(X) = \mathcal{P}^*(X)$. For $m = 1$, we know there must be a sequence $\mu_{11}, \mu_{12}, \dots$ of measures in \mathcal{P} such that $\mu_{1i}(X)$ converges to $\mathcal{P}^*(X)$. For the inductive step, if $m < n$, suppose we have constructed an appropriate sequence $\mu_{m1}, \mu_{m2}, \dots$. Consider the sequence of real numbers $\mu_{mi}(X_{m+1})$. Using the Bolzano-Weierstrass theorem (Rudin, 1976) (which says that every sequence of real numbers has a convergent subsequence), this sequence has a convergent subsequence. Let $\mu_{(m+1)1}, \mu_{(m+1)2}, \dots$ be the subsequence of $\mu_{m1}, \mu_{m2}, \dots$ which generates this convergent subsequence. This sequence of probability measures clearly has all the required properties. This completes the inductive step.

Define $\mu_X(Y) = \lim_{i \rightarrow \infty} \mu_{ni}(Y)$. It is easy to check that μ_X is indeed a probability measure, that $\mu_X(X) = \mathcal{P}^*(X)$, and if $\mathcal{P}' = \mathcal{P} \cup \{\mu_X\}$, that $\mathcal{P}^*(Y) = (\mathcal{P}')^*(Y)$ for all $Y \in \Sigma$. This shows that an appropriate set \mathcal{P}' exists.

Now, given π , let $M = (\Omega, \Sigma, \mathcal{P}, \pi)$ and $M' = (\Omega, \Sigma, \mathcal{P}', \pi)$. A straightforward induction on the structure of f shows that $M \models f$ iff $M' \models f$. For the base case:

$$\begin{aligned} & (\Omega, \Sigma, \mathcal{P}, \pi) \models a_1 l(\varphi_1) + \dots + a_n l(\varphi_n) \geq a \\ \Leftrightarrow & a_1 \mathcal{P}^*(\llbracket \varphi_1 \rrbracket_M) + \dots + a_n \mathcal{P}^*(\llbracket \varphi_n \rrbracket_M) \geq a \\ \Leftrightarrow & a_1 (\mathcal{P}')^*(\llbracket \varphi_1 \rrbracket_{M'}) + \dots + a_n (\mathcal{P}')^*(\llbracket \varphi_n \rrbracket_{M'}) \geq a \\ \Leftrightarrow & (\Omega, \Sigma, \mathcal{P}', \pi) \models a_1 l(\varphi_1) + \dots + a_n l(\varphi_n) \geq a. \end{aligned}$$

The others cases are trivial. ■

Just as in FHM, to prove Theorem 5.1, we make use of the following lemma which can be derived from Cramer's rule (Shores, 1999) and simple estimates on the size of the determinant (see also (Chvátal, 1983) for a simpler variant):

Lemma A.4: *If a system of r linear equalities and/or inequalities with integer coefficients each of length at most l has a nonnegative solution, then it has a nonnegative solution with at most r entries positive, and where the size of each member of the solution is $O(rl + r \log(r))$.*

Continuing with the proof of Theorem 5.1, suppose that f is satisfiable in an upper probability structure. By Proposition 4.1, the system \hat{f} of equality formulas has a solution, so f is satisfied in a upper probability structure with a finite state space. Thus, by Lemma A.3, f is satisfied in a structure $M = (\Omega, \Sigma, \mathcal{P}, \pi)$ such that for all $X \in \Sigma$, there exists $\mu_X \in \mathcal{P}$ such that $\mu_X(X) = \mathcal{P}^*(X)$.

As in the completeness proof, we can write f in disjunctive normal form. Each disjunct g is a conjunction of at most $|f| - 1$ basic likelihood formulas and their negations. Since $M \models f$, there must be some disjunct g such that $M \models g$. Suppose that g is the conjunction of r basic likelihood formulas and s negations of basic likelihood formulas. Let p_1, \dots, p_N

be the primitive formulas appearing in f . Let $\delta_1, \dots, \delta_{2^N}$ be the atoms over p_1, \dots, p_N . As in the proof of completeness, we derive a system of equalities and inequalities from g . It is a slightly more complicated system, however. Recall that each propositional formula over p_1, \dots, p_N is a disjunction of atoms. Let $\varphi_1, \dots, \varphi_k$ be the propositional formulas that appear in g . Notice that $k < |f|$ (since there are some symbols in f , such as the coefficients, that are not in the propositional formulas). The system of equations and inequalities we construct involve variables x_{ij} , where $i = 1, \dots, k$ and $j = 1, \dots, 2^N$. Intuitively, x_{ij} represents $\mu_{\llbracket \varphi_i \rrbracket_M}(\llbracket \delta^j \rrbracket_M)$, where $\mu_{\llbracket \varphi_i \rrbracket_M} \in \mathcal{P}$ is such that $\mu_{\llbracket \varphi_i \rrbracket_M}(\llbracket \varphi_i \rrbracket_M) = \mathcal{P}^*(\llbracket \varphi_i \rrbracket_M)$. Thus, the system includes $k < |f|$ equations of the following form,

$$x_{i1} + \dots + x_{i2^N} = 1,$$

for $i = 1, \dots, k$. Since $\mu_{\llbracket \varphi_i \rrbracket_M}(\llbracket \varphi_i \rrbracket_M) \geq \mu(\llbracket \varphi_i \rrbracket_M)$ for all $\mu \in \mathcal{P}$, if E_i is the subset of $\{1, \dots, 2^N\}$ such that $\varphi_i = \bigvee_{j \in E_i} \delta_j$, the system includes $k^2 - k$ inequalities of the form

$$\sum_{j \in E_i} x_{ij} \geq \sum_{j \in E_{i'}} x_{i'j},$$

for each pair i, i' such that $i \neq i'$. For each conjunct in g of the form $\theta_1 l(\varphi_1) + \dots + \theta_n l(\varphi_k) \geq \alpha$, there is a corresponding inequality where, roughly speaking, we replace $l(\varphi_i)$ by $\mu_{\llbracket \varphi_i \rrbracket_M}(\llbracket \varphi \rrbracket_M)$.⁸ Since $\mu_{\llbracket \varphi_i \rrbracket_M}$ corresponds to $\sum_{j \in E_i} x_{ij}$, the appropriate inequality is

$$\sum_{i=1}^k \theta_i \sum_{j \in E_i} x_{ij} \geq \alpha.$$

Negations of such formulas correspond to a negated inequality formula; as before, this is equivalent to a formula of the form

$$-(\sum_{i=1}^k \theta_i \sum_{j \in E_i} x_{ij}) > -\alpha.$$

Notice that there are at most $|f|$ inequalities corresponding to the conjuncts of g . Thus, altogether, there are at most $k(k-1) + 2|f| < |f|^2$ equations and inequalities in the system (since $k < |f|$). We know that the system has a nonnegative solution (taking x_j^i to be $\mu_{\llbracket \varphi_i \rrbracket_M}(\llbracket \delta^j \rrbracket_M)$). It follows from Lemma A.4 that the system has a solution $x^* = (x_{11}^*, \dots, x_{12^N}^*, \dots, x_{k1}^*, \dots, x_{k2^N}^*)$ with $t \leq |f|^2$ entries positive, and with each entry of size $O(|f|^2 |f| + |f|^2 \log(|f|))$.

We use this solution to construct a small structure satisfying the formula f . Let $I = \{i : x_{ij}^* \text{ is positive, for some } j\}$; suppose that $I = \{i_1, \dots, i_{t'}\}$, for some $t' \leq t$. Let $M = (S, E, \mathcal{P}, \pi)$ where S has t' states, say $s_1, \dots, s_{t'}$, and E consists of all subsets of S . Let $\pi(s_h)$ be the truth assignment corresponding to the formula δ_{i_h} , that is, $\pi(s_h)(p) = \mathbf{true}$ if and only if $\delta_{i_h} \Rightarrow p$ (and where $\pi(s_h)(p) = \mathbf{false}$ if p does not appear in f). Define $\mathcal{P} = \{\mu_j : 1 \leq i \leq k\}$, where $\mu_j(s_h) = x_{i_h j}^*$. It is clear from the construction that $M \models f$. Since $|\mathcal{P}| = k < |f|$, $|S| = t' \leq t \leq |f|^2$ and $\mu_j(s_h) = x_{i_h j}^*$, where, by construction, the size of $x_{i_h j}^*$ is $O(|f|^2 |f| + |f|^2 \log(|f|))$, the theorem follows. ■

8. For simplicity here, we are implicitly assuming that each of the formulas φ_i appears in each conjunct of g . This is without loss of generality, since if φ_i does not appear, we can put it in, taking $\theta_i = 0$.

Appendix B. Proof of the Characterization of Upper Probabilities

To make this paper self-contained, in this appendix we give a proof of Theorem 2.3. The proof we give is essentially that of Anger and Lembcke (1985). Walley (1991) gives an alternate proof along somewhat similar lines. Note that the functional \tilde{g} we define in our proof corresponds to the construction in Walley's Natural Extension Theorem, which is needed in his version of this result.

Theorem 2.3: *Suppose that Ω is a set, Σ is an algebra of subsets of Ω , and $v : \Sigma \rightarrow \mathbb{R}$. Then there exists a set \mathcal{P} of probability measures with $v = \mathcal{P}^*$ if and only if v satisfies the following three properties:*

- UP1. $v(\emptyset) = 0$,
- UP2. $v(\Omega) = 1$,
- UP3. *for all integers m, n, k and all subsets A_1, \dots, A_m in Σ , if $\{A_1, \dots, A_m\}$ is an (n, k) -cover of (A, Ω) , then $k + nv(A) \leq \sum_{i=1}^m v(A_i)$.*

Proof: The “if” direction of the characterization is straightforward. Given $\mathcal{P} = \{\mu_i\}_{i \in I}$ a set of probability measures, we show \mathcal{P}^* satisfies **UP1-UP3**.

- UP1:** $\mathcal{P}^*(\emptyset) = \sup\{\mu_i(\emptyset)\} = \sup\{0\} = 0$
- UP2:** $\mathcal{P}^*(\Omega) = \sup\{\mu_i(\Omega)\} = \sup\{1\} = 1$
- UP3:** Given A_1, \dots, A_m and A such that $A \subseteq \bigcup_{J \subseteq \{1, \dots, m\}, |J|=k+n} \bigcap_{j \in J} A_j$ and $\Omega \subseteq \bigcup_{J \subseteq \{1, \dots, m\}, |J|=k} \bigcap_{j \in J} A_j$, then for any i we have $k\mu_i(\Omega) + n\mu_i(A) \leq \sum_{j=1}^m \mu_i(A_j)$, that is $k + n\mu_i(A) \leq \sum_{j=1}^m \mu_i(A_j) \leq \sup_i \{\sum_{j=1}^m \mu_i(A_j)\} \leq \sum_{j=1}^m \sup_i \{\mu_i(A_j)\} = \sum_{j=1}^m \mathcal{P}^*(A_j)$. But $\sup_i \{k + n\mu_i(A)\} = k + n \sup_i \{\mu_i(A)\} = k + n\mathcal{P}^*(A)$, so $k + n\mathcal{P}^*(A) \leq \sum_{j=1}^m \mathcal{P}^*(A_j)$, as required.

As for the “only if” direction, we first prove a general lemma relating the problem to the Hahn-Banach Theorem. Some general definitions are needed. Suppose that we are given a space W and an algebra \mathcal{F} of subsets of W . Let \mathcal{K} be the vector space generated by the indicator functions 1_X defined by

$$1_X(x) = \begin{cases} 0 & \text{if } x \notin X \\ 1 & \text{if } x \in X, \end{cases}$$

for $X \in \mathcal{F}$. A *sublinear functional on \mathcal{K}* is a mapping $c : \mathcal{K} \rightarrow \mathbb{R}$ such that $c(\alpha h) = \alpha c(h)$ for $\alpha \geq 0$ and $c(h_1 + h_2) \leq c(h_1) + c(h_2)$ for all h_1, h_2 . A sublinear functional is *increasing* if $h \geq 0$ implies $c(h + h') \geq c(h')$ for all $h' \in \mathcal{K}$. The following result is a formulation of the well-known Hahn-Banach Theorem (see, for example, (Conway, 1990)).

Theorem (Hahn-Banach): *Let \mathcal{K} be a vector space over \mathbb{R} , and let g be a sublinear functional on \mathcal{K} . If \mathcal{M} is a linear subspace in \mathcal{K} and $\lambda : \mathcal{M} \rightarrow \mathbb{R}$ is a linear functional such that $\lambda(x) \leq g(x)$ for all x in \mathcal{M} , then there is a linear functional $\lambda' : \mathcal{K} \rightarrow \mathbb{R}$ such that $\lambda'|_{\mathcal{M}} = \lambda$ and $\lambda'(x) \leq g(x)$ for all x in \mathcal{K} .*

Lemma B.1: *Let $g : \mathcal{F} \rightarrow [0, 1]$ be such that $g(W) = 1$ and suppose that there is an increasing sublinear functional \tilde{g} on \mathcal{K} such that*

1. $\tilde{g}(1_K) = g(K)$ for $K \in \mathcal{F}$;
2. $\tilde{g}(h) \leq 0$ if $h \leq 0$;
3. $\tilde{g}(-1) \leq -1$ (where $\tilde{g}(\alpha)$ is identified with $\tilde{g}(\alpha 1_W)$).

Then g is an upper probability measure.

Proof: We show that g is an upper probability by exhibiting a set $\{\mu_X : X \in \Sigma\}$ of probability measures, with the property that $\mu_X(X) = g(X)$ and $\mu_X(Y) \leq g(X)$ for $Y \neq X$. Each probability measure μ_X is constructed through an application of the Hahn-Banach Theorem.

Given $X \in \mathcal{F}$, define the linear functional λ on the subspace generated by 1_X by $\lambda(\alpha 1_X) = \alpha \tilde{g}(1_X)$. We claim that $\lambda(h) \leq \tilde{g}(h)$ for all h in the subspace. Since the elements of the subspace have the form $\alpha 1_X$, there are two cases to consider: $\alpha \geq 0$ and $\alpha < 0$. If $\alpha \geq 0$, then $\lambda(\alpha 1_X) = \alpha \tilde{g}(1_X) = \tilde{g}(\alpha 1_X)$, since \tilde{g} is sublinear. Moreover, $0 = \tilde{g}(0) = \tilde{g}(-1_X + 1_X) \leq \tilde{g}(-1_X) + \tilde{g}(1_X)$, so $\tilde{g}(-1_X) \geq -\tilde{g}(1_X)$. Thus, if $\alpha > 0$, then

$$\lambda(-\alpha 1_X) = -\alpha \tilde{g}(1_X) \leq \alpha \tilde{g}(-1_X) = \tilde{g}(-\alpha 1_X).$$

Now, by the Hahn-Banach Theorem, we can extend λ to a linear functional λ' on all of \mathcal{K} such that $\lambda'(h) \leq \tilde{g}(h)$ for all h . We claim that (a) $\lambda'(1_Y) \geq 0$ for all $Y \in \mathcal{K}$ and (b) $\lambda'(1) = 1$. For (a), note that $\lambda'(-1_Y) \leq \tilde{g}(-1_Y) \leq 0$ by assumption, so $\lambda'(1_Y) \geq 0$. For (b), note that $\lambda'(1) \leq \tilde{g}(1) = g(W) = 1$ and that $\lambda'(1) = -\lambda'(-1) \geq -\tilde{g}(-1) \geq 1$ (since $\tilde{g}(-1) \leq -1$, by assumption).

Define $\mu_X(Y) = \lambda'(1_Y)$. Since $\lambda'(1_W) = 1$, $\mu_X(W) = 1$. If Y and Y' are disjoint, it is immediate from the linearity of λ that $\mu_X(Y \cup Y') = \mu_X(Y) + \mu_X(Y')$. By construction, $\mu_X(Y) \leq \tilde{g}(1_Y) = g(Y)$ for any $Y \neq X$, and $\mu_X(X) = \lambda(1_X) = \tilde{g}(1_X) = g(X)$. Bottom line: there is a probability measure μ_X dominated by g such that $\mu_X(X) = g(X)$.

Take $\mathcal{P} = \{\mu_X : X \in \Sigma\}$. Since for any X we have that $\mu_X(X) = g(X)$ and $\mu_X(Y) \leq g(X)$ (if $Y \neq X$), we have $\mathcal{P}^*(X) = \mu_X(X) = g(X)$. Therefore, $g = \mathcal{P}^*$. ■

The main result follows by showing how to construct, from a function v satisfying the properties of Theorem 2.3, a sublinear functional c on \mathcal{K} with the required properties.

Suppose that $g : \Sigma \rightarrow \mathbb{R}$ is a function satisfying **UP1-UP3**. As we show in the discussion after Theorem 2.3 in the text, **UP1-UP3** show that the range of g is in fact $[0, 1]$. Since g satisfies **UP3**, if $\{K_1, \dots, K_m\}$ is an (n, k) -cover of (K, Ω) , we have $k + ng(K) \leq \sum_{i=1}^m K_i$. This is equivalent to saying that $k + n1_K \leq \sum_{i=1}^m 1_{K_i}$. Hence, for all K_1, \dots, K_m such that $k + n1_K \leq \sum_{i=1}^m 1_{K_i}$, we have $k + ng(K) \leq \sum_{i=1}^m g(K_i)$, or equivalently

$$-\frac{k}{n} + \frac{1}{n} \sum_{i=1}^m g(K_i) \geq g(K). \quad (3)$$

This observation motivates the following definition of the functional $\tilde{g} : \mathcal{K} \rightarrow \mathbb{R} \cup \{-\infty, \infty\}$:

$$\tilde{g}(h) = \inf \left\{ -\frac{k}{n} + \frac{1}{n} \sum_{i=1}^m g(K_i) : m, n, k \in \mathbb{N}, m, n > 0, K_1, \dots, K_m \in \mathcal{F}, -\frac{k}{n} + \frac{1}{n} \sum_{i=1}^m 1_{K_i} \geq h \right\}.$$

Our goal now is to show that \tilde{g} satisfies the conditions of Lemma B.1.

- It is almost immediate from the definitions that \tilde{g} is increasing: if $h \geq 0$ and $-\frac{k}{n} + \frac{1}{n} \sum_{i=1}^m 1_{K_i} \geq h + h'$, then $-\frac{k}{n} + \frac{1}{n} \sum_{i=1}^m 1_{K_i} \geq h'$.
- To see that \tilde{g} is sublinear, note that it is easy to see using the properties of \inf that $\tilde{g}(h_1 + h_2) \leq \tilde{g}(h_1) + \tilde{g}(h_2)$. To show that $\tilde{g}(\alpha h) = \alpha \tilde{g}(h)$ for $\alpha \geq 0$, first observe that the definition of \tilde{g} is equivalent to

$$\inf \left\{ -\beta + \sum_{i=1}^m \beta_i g(K_i) : m \in \mathbb{N}, \beta, \beta_i \in \mathbb{R}_+, K_1, \dots, K_m \in \mathcal{F} - \beta + \sum_{i=1}^m \beta_i 1_{K_i} \geq h \right\}.$$

Consider first the case $\alpha > 0$. Then

$$\begin{aligned} \tilde{g}(\alpha h) &= \inf \left\{ -\beta + \sum_{i=1}^m \beta_i g(K_i) : -\beta + \sum_{i=1}^m \beta_i 1_{K_i} \geq \alpha h \right\} \\ &= \inf \left\{ -\beta + \sum_{i=1}^m \beta_i g(K_i) : -\frac{\beta}{\alpha} + \frac{1}{\alpha} \sum_{i=1}^m \beta_i 1_{K_i} \geq h \right\} \\ &= \alpha \inf \left\{ -\frac{\beta}{\alpha} + \frac{1}{\alpha} \sum_{i=1}^m \beta_i g(K_i) : -\frac{\beta}{\alpha} + \frac{1}{\alpha} \sum_{i=1}^m \beta_i 1_{K_i} \geq h \right\} \\ &= \alpha \tilde{g}(h). \end{aligned}$$

For $\alpha = 0$, it is clear from the definition of \tilde{g} that $\tilde{g}(1_\emptyset) \leq g(\emptyset)$. From (3) it follows that $\tilde{g}(1_\emptyset) \geq g(\emptyset)$, and hence $\tilde{g}(0) = \tilde{g}(1_\emptyset) = g(\emptyset) = 0$.

- It is immediate from the definition of \tilde{g} that $\tilde{g}(1_K) \leq g(K)$ for $K \in \mathcal{F}$; the fact that $\tilde{g}(1_K) = g(K)$ now follows from (3).
- It is immediate from the definition that $\tilde{g}(-1) \leq -1$.
- If $h \leq 0$, then $-h \geq 0$; since \tilde{g} is increasing, $\tilde{g}(h) \leq \tilde{g}(-h + h) = \tilde{g}(0)$, and since \tilde{g} is sublinear, $\tilde{g}(0) = 0$.

Since the conditions of Lemma B.1 are satisfied, g is an upper probability measure. ■
