

# On Hoare Logic and Kleene Algebra with Tests

Dexter Kozen  
Cornell University

---

We show that Kleene algebra with tests (KAT) subsumes propositional Hoare logic (PHL). Thus the specialized syntax and deductive apparatus of Hoare logic are inessential and can be replaced by simple equational reasoning. In addition, we show that all relationally valid inference rules are derivable in KAT and that deciding the relational validity of such rules is *PSPACE*-complete.

Categories and Subject Descriptors: D.2.2 [Software Engineering]: Tools and Techniques—*structured programming*; D.2.4 [Software Engineering]: Program Verification—*correctness proofs*; D.3.3 [Software Engineering]: Language Constructs and Features—*control structures*; F.3.1 [Logics and Meanings of Programs]: Specifying and Verifying and Reasoning about Programs—*assertions; invariants; logics of programs; mechanical verification; pre- and postconditions; specification techniques*; F.3.2 [Logics and Meanings of Programs]: Semantics of Programming Languages—*algebraic approaches to semantics*; F.3.3 [Logics and Meanings of Programs]: Studies of Program Constructs—*control primitives*; I.1.1 [Algebraic Manipulation]: Expressions and Their Representations—*simplification of expressions*; I.1.3 [Algebraic Manipulation]: Languages and Systems—*special-purpose algebraic systems*; I.2.2 [Algebraic Manipulation]: Automatic Programming—*program modification; program synthesis; program transformation; program verification*

General Terms: Design, Languages, Theory, Verification

Additional Key Words and Phrases: Dynamic logic, Hoare logic, Kleene algebra, Kleene algebra with tests, specification

---

## 1. INTRODUCTION

*Hoare logic*, introduced by C. A. R. Hoare in 1969 [Hoare 1969], was the first formal system for the specification and verification of well-structured programs. This pioneering work initiated the field of program correctness and inspired dozens of technical articles [Cook 1978; Clarke et al. 1983; Cousot 1990]. For this achievement among others, Hoare received the Turing Award in 1980.

Hoare logic uses a specialized syntax involving *partial correctness assertions*

(PCAs) of the form  $\{b\} p \{c\}$  and a deductive apparatus consisting of a system of specialized rules of inference. Under certain conditions, these rules are relatively complete [Cook 1978]; essentially, the propositional fragment of the logic can be used to reduce partial correctness assertions to static assertions about the underlying domain of computation.

In this paper we show that this propositional fragment, which we call *propositional Hoare logic* (PHL), is subsumed by *Kleene algebra with tests* (KAT), an equational algebraic system introduced in [Kozen 1997]. The reduction transforms PCAs to ordinary equations and the specialized rules of inference to equational implications (universal Horn formulas). The transformed rules are all derivable in KAT by pure equational reasoning. More generally, we show that all Hoare-style inference rules of the form

$$\frac{\{b_1\} p_1 \{c_1\}, \dots, \{b_n\} p_n \{c_n\}}{\{b\} p \{c\}} \quad (1)$$

that are valid over relational models are derivable in KAT; this is trivially false for PHL. We also show that deciding the relational validity of such rules is *PSPACE*-complete.

A Kleene algebra with tests is defined simply as a Kleene algebra with an embedded Boolean subalgebra. Possible interpretations include the various standard relational and trace-based models used in program semantics, and KAT is complete for the equational theory of these models [Kozen and Smith 1996]. This work shows that the reasoning power represented by propositional Hoare logic is captured in a concise, purely equational system KAT that is complete over various natural classes of interpretations and whose exact complexity is known. Thus for all practical purposes KAT can be used in place of the Hoare rules in program correctness proofs.

### 1.1 Related Work

Equational logic possesses a rich theory and is the subject of numerous papers and texts [Taylor 1979]. Its power and versatility in program specification and verification are widely recognized [O'Donnell 1985; Goguen and Malcolm 1996].

The equational nature of Hoare logic has been observed previously. Manes and Arbib [Manes and Arbib 1986] formulate Hoare logic in partially additive semirings and categories. The encoding of the PCA  $\{b\} p \{c\}$  as the equation  $bp\bar{c} = 0$  is observed there. They consider only relational models and the treatment of iteration is infinitary. Bloom and Ésik [Bloom and Ésik 1991] reduce Hoare logic to the equational logic of iteration theories. They do not restrict their attention to **while** programs but capture all flowchart schemes, requiring extra notation for insertion, tupling, and projection. Their development is done in the framework of category theory. Semantic models consist of morphisms in algebraic theories, a particular kind of category. Other related work can be found in [Bloom and Ésik 1992; Main and Black 1990].

The encoding of the **while** programming constructs using the regular operators and tests originated with propositional dynamic logic (PDL) [Fischer and Ladner 1979]. Although strictly less expressive than PDL, KAT has a number of advantages: (i) it isolates the equational part of PDL, allowing program equivalence proofs to be expressed in their natural form; (ii) it conveniently overloads the operators  $+$ ,  $\cdot$ ,  $0$ ,  $1$ ,

allowing concise and elegant algebraic proofs; (iii) it is *PSPACE*-complete [Cohen et al. 1996], whereas PDL is *EXPTIME*-complete [Fischer and Ladner 1979]; (iv) interpretations are not restricted to relational models, but may be any algebraic structure satisfying the axioms; and (v) it admits various general and useful algebraic constructions such as the formation of algebras of matrices over a KAT, which among other things allows a natural encoding of automata.

Halpern and Reif [Halpern and Reif 1983] prove *PSPACE*-completeness of strict deterministic PDL, but neither the upper nor the lower bound of our *PSPACE*-completeness result follows from theirs. Not only are PDL semantics restricted to relational models, but the arguments of [Halpern and Reif 1983] depend on an additional nonalgebraic restriction: the relations interpreting atomic programs must be single-valued. Without this restriction, even if only **while** programs are allowed, PDL is exponential time hard. In contrast, KAT imposes no such restrictions.

In Section 2 we review the definitions of Hoare logic and Kleene algebra with tests. In Section 3 we reduce PHL to KAT and derive the Hoare rules as theorems of KAT. In Section 4 we strengthen this result to show that KAT is complete for relationally valid rules of the form (1). In Section 5 we prove that the problem of deciding the relational validity of such rules is *PSPACE*-complete.

## 2. PRELIMINARY DEFINITIONS

### 2.1 Hoare Logic

Hoare logic is a system for reasoning inductively about well-structured programs. A comprehensive introduction can be found in [Cousot 1990].

A common choice of programming language in Hoare logic is the language of **while** programs. The first-order version of this language contains a simple assignment  $x := e$ , conditional test **if**  $b$  **then**  $p$  **else**  $q$ , sequential composition  $p ; q$ , and a looping construct **while**  $b$  **do**  $p$ .

The basic assertion of Hoare logic is the *partial correctness assertion* (PCA)

$$\{b\} p \{c\}, \tag{2}$$

where  $b$  and  $c$  are formulas and  $p$  is a program. Intuitively, this statement asserts that whenever  $b$  holds before the execution of the program  $p$ , then if and when  $p$  halts,  $c$  is guaranteed to hold of the output state. It does not assert that  $p$  must halt.

Semantically, programs  $p$  in Hoare logic and dynamic logic (DL) are usually interpreted as binary input/output relations  $p^{\mathcal{M}}$  on a domain of computation  $\mathcal{M}$ , and assertions are interpreted as subsets of  $\mathcal{M}$  [Cook 1978; Pratt 1978]. The definition of the relation  $p^{\mathcal{M}}$  is inductive on the structure of  $p$ ; for example,  $(p ; q)^{\mathcal{M}} = p^{\mathcal{M}} \circ q^{\mathcal{M}}$ , the ordinary relational composition of the relations corresponding to  $p$  and  $q$ . The meaning of the PCA (2) is the same as the meaning of the DL formula  $b \rightarrow [p]c$ , where  $\rightarrow$  is ordinary propositional implication and the modal construct  $[p]c$  is interpreted in the model  $\mathcal{M}$  as the set of states  $s$  such that for all  $(s, t) \in p^{\mathcal{M}}$ , the output state  $t$  satisfies  $c$ .

Hoare logic provides a system of specialized rules for deriving valid PCAs, one rule for each programming construct. The verification process is inductive on the structure of programs. The traditional Hoare inference rules are:

*Assignment rule.*

$$\{b[x/e]\} x := e \{b\} \quad (3)$$

*Composition rule.*

$$\frac{\{b\} p \{c\}, \quad \{c\} q \{d\}}{\{b\} p ; q \{d\}} \quad (4)$$

*Conditional rule.*

$$\frac{\{b \wedge c\} p \{d\}, \quad \{\neg b \wedge c\} q \{d\}}{\{c\} \text{ if } b \text{ then } p \text{ else } q \{d\}} \quad (5)$$

*While rule.*

$$\frac{\{b \wedge c\} p \{c\}}{\{c\} \text{ while } b \text{ do } p \{\neg b \wedge c\}} \quad (6)$$

*Weakening rule.*

$$\frac{b' \rightarrow b, \quad \{b\} p \{c\}, \quad c \rightarrow c'}{\{b'\} p \{c'\}} \quad (7)$$

Propositional Hoare logic (PHL) consists of atomic proposition and program symbols, the usual propositional connectives, **while** program constructs, and PCAs built from these. Atomic programs are interpreted as binary relations on a set  $\mathcal{M}$  and atomic propositions are interpreted as subsets of  $\mathcal{M}$ . The deduction system of PHL consists of the composition, conditional, while, and weakening rules (4)–(7) and propositional logic. The assignment rule (3) is omitted, since there is no first-order relational structure over which to interpret program variables; in practice, its role is played by PCAs over atomic programs that are postulated as assumptions.

In PHL, we are concerned with the problem of determining the validity of rules of the form

$$\frac{\{b_1\} p_1 \{c_1\}, \dots, \{b_n\} p_n \{c_n\}}{\{b\} p \{c\}} \quad (8)$$

over relational interpretations. The premises  $\{b_i\} p_i \{c_i\}$  take the place of the assignment rule (3) and are an essential part of the formulation.

## 2.2 Kleene Algebra

Kleene algebra (KA) is the algebra of regular expressions [Kleene 1956; Conway 1971]. The axiomatization used here is from [Kozen 1994]. A *Kleene algebra* is an algebraic structure  $(\mathcal{K}, +, \cdot, *, 0, 1)$  that is an idempotent semiring under  $+$ ,  $\cdot$ ,  $0, 1$  satisfying

$$1 + pp^* = p^* \quad (9)$$

$$1 + p^*p = p^* \quad (10)$$

$$q + pr \leq r \rightarrow p^*q \leq r \quad (11)$$

$$q + rp \leq r \rightarrow qp^* \leq r \quad (12)$$

where  $\leq$  refers to the natural partial order on  $\mathcal{K}$ :

$$p \leq q \stackrel{\text{def}}{\iff} p + q = q.$$

The operation  $+$  gives the supremum with respect to the natural order  $\leq$ . Instead of (11) and (12), we might take the equivalent axioms

$$pr \leq r \rightarrow p^*r \leq r \quad (13)$$

$$rp \leq r \rightarrow rp^* \leq r. \quad (14)$$

These axioms say essentially that  $*$  behaves like the Kleene asterate operator of formal language theory or the reflexive transitive closure operator of relational algebra.

Kleene algebra is a versatile system with many useful interpretations. Standard models include the family of regular sets over a finite alphabet; the family of binary relations on a set; and the family of  $n \times n$  matrices over another Kleene algebra. Other more unusual interpretations include the  $\min, +$  algebra used in shortest path algorithms and models consisting of convex polyhedra used in computational geometry [Iwano and Steiglitz 1990].

The following are some typical identities that hold in all Kleene algebras:

$$(p^*q)^*p^* = (p+q)^* \quad (15)$$

$$p(qp)^* = (pq)^*p \quad (16)$$

$$(pq)^* = 1 + p(qp)^*q \quad (17)$$

$$p^* = (pp)^*(1+p). \quad (18)$$

All the operators are monotone with respect to  $\leq$ . In other words, if  $p \leq q$ , then  $pr \leq qr$ ,  $rp \leq rq$ ,  $p+r \leq q+r$ , and  $p^* \leq q^*$  for any  $r$ .

The completeness result of [Kozen 1994] says that all true identities between regular expressions interpreted as regular sets of strings are derivable from the axioms of Kleene algebra. In other words, the algebra of regular sets of strings over the finite alphabet  $\Sigma$  is the free Kleene algebra on generators  $\Sigma$ . The axioms are also complete for the equational theory of relational models.

See [Kozen 1994] for a more thorough introduction.

### 2.3 Kleene Algebra with Tests

*Kleene algebras with tests* (KAT) were introduced in [Kozen 1997] and their theory further developed in [Kozen and Smith 1996; Cohen et al. 1996]. A Kleene algebra with tests is just a Kleene algebra with an embedded Boolean subalgebra. That is, it is a two-sorted structure

$$(\mathcal{K}, \mathcal{B}, +, \cdot, *, \bar{\phantom{x}}, 0, 1)$$

such that

- $(\mathcal{K}, +, \cdot, *, 0, 1)$  is a Kleene algebra,
- $(\mathcal{B}, +, \cdot, \bar{\phantom{x}}, 0, 1)$  is a Boolean algebra, and
- $\mathcal{B} \subseteq \mathcal{K}$ .

The Boolean complementation operator  $\bar{\phantom{x}}$  is defined only on  $\mathcal{B}$ . Elements of  $\mathcal{B}$  are called *tests*. The letters  $p, q, r, s$  denote arbitrary elements of  $\mathcal{K}$  and  $a, b, c$  denote tests.

This deceptively simple definition actually carries a lot of information in a concise package. The operators  $+, \cdot, 0, 1$  each play two roles: applied to arbitrary elements

of  $\mathcal{K}$ , they refer to nondeterministic choice, composition, fail, and skip, respectively; and applied to tests, they take on the additional meaning of Boolean disjunction, conjunction, falsity, and truth, respectively. These two usages do not conflict—for example, sequential testing of  $b$  and  $c$  is the same as testing their conjunction—and their coexistence admits considerable economy of expression.

The encoding of the **while** program constructs is as in PDL [Fischer and Ladner 1979]:

$$p ; q \stackrel{\text{def}}{=} pq \tag{19}$$

$$\mathbf{if } b \mathbf{ then } p \mathbf{ else } q \stackrel{\text{def}}{=} bp + \bar{b}q \tag{20}$$

$$\mathbf{while } b \mathbf{ do } p \stackrel{\text{def}}{=} (bp)^*\bar{b}. \tag{21}$$

For applications in program verification, the standard interpretation would be a Kleene algebra of binary relations on a set and the Boolean algebra of subsets of the identity relation. One could also consider trace models, in which the Kleene elements are sets of traces (sequences of states) and the Boolean elements are sets of states (traces of length 0). As with KA, one can form the algebra  $\text{Mat}(\mathcal{K}, \mathcal{B}, n)$  of  $n \times n$  matrices over a KAT  $(\mathcal{K}, \mathcal{B})$ ; the Boolean elements of this structure are the diagonal matrices over  $\mathcal{B}$ . There is also a language-theoretic model that plays the same role in KAT that the regular sets of strings over a finite alphabet play in KA, namely the family of regular sets of *guarded strings* over a finite alphabet  $\Sigma$  with guards from a set  $\mathcal{B}$ . This is the free KAT on generators  $\Sigma, \mathcal{B}$ ; that is, the equational theory of this structure is exactly the set of all equational consequences of the KAT axioms. Moreover, KAT is complete for the equational theory of relational models [Kozen and Smith 1996].

### 3. KAT AND HOARE LOGIC

In this section we encode Hoare logic in KAT and derive the Hoare composition, conditional, while, and weakening rules as theorems of KAT. We will strengthen this result in Section 4 by showing that KAT can derive all relationally valid rules of the form (8).

The PCA  $\{b\} p \{c\}$  is encoded in KAT by the equation

$$bp\bar{c} = 0. \tag{22}$$

Intuitively, this says that the program  $p$  with preguard  $b$  and postguard  $\bar{c}$  has no halting execution. An equivalent formulation is

$$bp = bpc, \tag{23}$$

which says intuitively that testing  $c$  after executing  $bp$  is always redundant.

The equivalence of (22) and (23) can be argued easily in KAT. This equivalence was previously observed by Manes and Arbib [Manes and Arbib 1986]. Assuming (22),

$$\begin{aligned} bp &= bp(c + \bar{c}) && \text{by the axiom } a1 = a \text{ and Boolean algebra} \\ &= bpc + bp\bar{c} && \text{by distributivity} \\ &= bpc && \text{by (22) and the axiom } a + 0 = a. \end{aligned}$$

Conversely, assuming (23),

$$\begin{aligned} bp\bar{c} &= bpc\bar{c} && \text{by (23)} \\ &= bp0 && \text{by associativity and Boolean algebra} \\ &= 0 && \text{by the axiom } a0 = 0. \end{aligned}$$

The equation (23) is equivalent to the inequality  $bp \leq bpc$ , since the reverse inequality is a theorem of KAT; it follows immediately from the axiom  $c \leq 1$  of Boolean algebra and monotonicity of multiplication.

Using (19)–(21) and (23), the Hoare rules (4)–(7) take the following form:

*Composition rule:*

$$bp = bpc \wedge cq = cqd \rightarrow bpq = bpqd \quad (24)$$

*Conditional rule:*

$$bcp = bcpd \wedge \bar{b}cq = \bar{b}cqd \rightarrow c(bp + \bar{b}q) = c(bp + \bar{b}q)d \quad (25)$$

*While rule:*

$$bcp = bcpc \rightarrow c(bp)^*\bar{b} = c(bp)^*\bar{b}\bar{b}c \quad (26)$$

*Weakening rule:*

$$b' \leq b \wedge bp = bpc \wedge c \leq c' \rightarrow b'p = b'pc'. \quad (27)$$

These implications are to be interpreted as universal Horn formulas; that is, the variables are implicitly universally quantified. To establish the adequacy of the translation, we show that (24)–(27) encoding the Hoare rules (4)–(7) are theorems of KAT.

**THEOREM 3.1.** *The universal Horn formulas (24)–(27) are theorems of KAT.*

**PROOF.** First we derive (24). Assuming the premises

$$bp = bpc \quad (28)$$

$$cq = cqd, \quad (29)$$

we have

$$\begin{aligned} bpq &= bpcq && \text{by (28)} \\ &= bpcqd && \text{by (29)} \\ &= bpqd && \text{by (28)}. \end{aligned}$$

Thus the implication (24) holds.

For (25), assume the premises

$$bcp = bcpd \quad (30)$$

$$\bar{b}cq = \bar{b}cqd, \quad (31)$$

Then

$$\begin{aligned} c(bp + \bar{b}q) &= cbp + c\bar{b}q && \text{by distributivity} \\ &= bcp + \bar{b}cq && \text{by commutativity of tests} \end{aligned}$$

$$\begin{aligned}
&= bcpd + \bar{b}cqd && \text{by (30) and (31)} \\
&= cbpd + \bar{c}bqd && \text{by commutativity of tests} \\
&= c(bp + \bar{b}q)d && \text{by distributivity.}
\end{aligned}$$

For (26), by trivial simplifications it suffices to show

$$cbp \leq cbpc \rightarrow c(bp)^* \leq c(bp)^*c.$$

Assume

$$cbp \leq cbpc. \tag{32}$$

By (12) we need only show

$$c + c(bp)^*cbp \leq c(bp)^*c.$$

But

$$\begin{aligned}
c + c(bp)^*cbp &\leq c + c(bp)^*cbpc && \text{by (32) and monotonicity} \\
&\leq c1c + c(bp)^*cbpc && \text{by Boolean algebra} \\
&\leq c(1 + (bp)^*cbp)c && \text{by distributivity} \\
&\leq c(1 + (bp)^*bp)c && \text{by monotonicity} \\
&\leq c(bp)^*c && \text{by (10).}
\end{aligned}$$

Finally, for (27), we can rewrite the rule as

$$b' \leq b \wedge bp\bar{c} = 0 \wedge \bar{c}' \leq \bar{c} \rightarrow b'p\bar{c}' = 0,$$

which follows immediately from the monotonicity of multiplication.  $\square$

#### 4. A COMPLETENESS THEOREM

Theorem 3.1 says that for any proof rule of PHL, or more generally, for any rule of the form

$$\frac{\{b_1\} p_1 \{c_1\}, \dots, \{b_n\} p_n \{c_n\}}{\{b\} p \{c\}}$$

derivable in PHL, the corresponding equational implication (universal Horn formula)

$$b_1p_1\bar{c}_1 = 0 \wedge \dots \wedge b_np_n\bar{c}_n = 0 \rightarrow bp\bar{c} = 0 \tag{33}$$

is a theorem of KAT. In this section we strengthen this result to show (Corollary 4.2) that *all* universal Horn formulas of the form

$$r_1 = 0 \wedge \dots \wedge r_n = 0 \rightarrow p = q \tag{34}$$

that are relationally valid (true in all relational models) are theorems of KAT; in other words, KAT is complete for universal Horn formulas of the form (34) over relational interpretations. This result subsumes Theorem 3.1, since the Hoare rules are relationally valid. Corollary 4.2 is trivially false for PHL; for example, the rule

$$\frac{\{c\} \mathbf{if } b \mathbf{ then } p \mathbf{ else } p \{c\}}{\{c\} p \{c\}}$$

is not derivable, since the Hoare rules only increase the length of programs.

In [Kozen and Smith 1996], based on a technique of Cohen [Cohen 1994] for KA, we showed that a formula of KAT of the form (34) is valid over all models iff it is valid over \*-continuous models; moreover, its validity over either class of models is equivalent to the validity of a pure equation. We strengthen this result by showing that this equivalence still holds when models are further restricted to relational models. The deductive completeness of KAT over relationally valid formulas of the form (34) follows as a corollary.

Let  $T_{\Sigma, \mathbf{B}}$  denote the set of terms of the language of KAT over primitive propositions  $\Sigma = \{a_1, \dots, a_m\}$  and primitive tests  $\mathbf{B} = \{b_1, \dots, b_k\}$ . Let  $r_1, \dots, r_n, p, q \in T_{\Sigma, \mathbf{B}}$ . Let  $u = (a_1 + \dots + a_m)^*$  and let  $r = \sum_i r_i$ . The formula (34) is equivalent to  $r = 0 \rightarrow p = q$ . Consider the four conditions

$$\text{KAT} \models r = 0 \rightarrow p = q, \quad (35)$$

$$\text{KAT}^* \models r = 0 \rightarrow p = q, \quad (36)$$

$$\text{REL} \models r = 0 \rightarrow p = q, \quad (37)$$

$$\models p + uru = q + uru. \quad (38)$$

It does not matter whether (38) is preceded by KAT,  $\text{KAT}^*$ , or REL, since the equational theories of these classes coincide [Kozen and Smith 1996]. It was shown in [Kozen and Smith 1996] that the metastatements (35), (36), and (38) are equivalent. We wish to add (37) to this list.

The algebra  $\mathcal{G}_{\Sigma, \mathbf{B}}$  of regular sets of guarded strings over  $\Sigma, \mathbf{B}$  and the standard interpretation  $G : T_{\Sigma, \mathbf{B}} \rightarrow \mathcal{G}_{\Sigma, \mathbf{B}}$  were defined in [Kozen and Smith 1996]. We briefly review the definitions here. An *atom* of  $\mathbf{B}$  is a term of the form  $c_1 c_2 \dots c_k$ , where  $c_i$  is either  $b_i$  or  $\bar{b}_i$ . An atom represents an atom of the free Boolean algebra generated by  $\mathbf{B}$ . Atoms are denoted  $\alpha, \beta, \dots$ . A *guarded string* over  $\Sigma, \mathbf{B}$  is a term of the form

$$\beta_0 p_0 \beta_1 p_1 \beta_2 \dots \beta_{n-1} p_{n-1} \beta_n,$$

where each  $p_i \in \Sigma$  and each  $\beta_i$  is an atom. This includes the case  $n = 0$ , so atoms are guarded strings. If  $x\alpha, \beta y$  are guarded strings and  $\alpha = \beta$ , then their product is  $x\alpha y$ . If  $\alpha \neq \beta$ , then the product does not exist. We can form the Kleene algebra of all sets of guarded strings with operations

$$\begin{aligned} A + B &\stackrel{\text{def}}{=} A \cup B \\ AB &\stackrel{\text{def}}{=} \{x\beta y \mid x\beta \in A, \beta y \in B\} \\ A^* &\stackrel{\text{def}}{=} \bigcup_n A^n \\ 0 &\stackrel{\text{def}}{=} \emptyset \\ 1 &\stackrel{\text{def}}{=} \{\text{atoms of } \mathbf{B}\}. \end{aligned}$$

This becomes a KAT by taking the Boolean algebra of tests to be the powerset of the set 1. The map  $G$  is defined to be the unique homomorphic map on  $T_{\Sigma, \mathbf{B}}$  extending

$$G(a) \stackrel{\text{def}}{=} \{\alpha a \beta \mid \alpha, \beta \text{ are atoms of } \mathbf{B}\}, \quad a \in \Sigma$$

$$G(b) \stackrel{\text{def}}{=} \{\beta \mid \beta \leq b\}, \quad b \in \mathbf{B},$$

where  $\beta \leq b$  denotes that  $b$  occurs positively in  $\beta$ . The algebra  $\mathcal{G}_{\Sigma, \mathbf{B}}$  is defined to be the image of  $T_{\Sigma, \mathbf{B}}$  under the map  $G$ . It was shown in [Kozen and Smith 1996] that  $\mathcal{G}_{\Sigma, \mathbf{B}}$  is the free KAT on generators  $\Sigma, \mathbf{B}$  in the sense that for any terms  $s, t \in T_{\Sigma, \mathbf{B}}$ ,

$$\models s = t \iff G(s) = G(t). \quad (39)$$

Note that  $G(u)$  is the set of all guarded strings over  $\Sigma, \mathbf{B}$ .

**THEOREM 4.1.** *The metastatements (35)–(38) are equivalent.*

**PROOF.** Since  $\text{REL} \subseteq \text{KAT}^* \subseteq \text{KAT}$ , the implications (35)  $\rightarrow$  (36)  $\rightarrow$  (37) hold trivially. Also, it is clear that

$$\text{KAT} \models p + uru = q + uru \rightarrow (r = 0 \rightarrow p = q),$$

therefore (38)  $\rightarrow$  (35) as well. It thus remains to show that (37)  $\rightarrow$  (38). Writing equations as pairs of inequalities, it suffices to show

$$\text{REL} \models r = 0 \rightarrow p \leq q \Rightarrow \models p \leq q + uru. \quad (40)$$

To show (40), we construct a relational model  $\mathcal{R}$  on states  $G(u) - G(uru)$ . Note that if  $x, y, z \in G(u)$  such that  $xyz \in G(u) - G(uru)$ , then  $y \in G(u) - G(uru)$ . If  $G(u) \subseteq G(uru)$ , then we are done, since in that case  $G(p) \subseteq G(u) \subseteq G(uru)$  and the right-hand side of (40) follows immediately from (39). Similarly, if  $G(1) \subseteq G(uru)$ , then  $G(u) \subseteq G(uru) \subseteq G(uru)$  and the same argument applies. We can therefore assume without loss of generality that both  $G(u) - G(uru)$  and  $G(1) - G(uru)$  are nonempty.

The atomic symbols are interpreted in  $\mathcal{R}$  as follows:

$$\begin{aligned} R(a) &\stackrel{\text{def}}{=} \{(x, xa\beta) \mid xa\beta \in G(u) - G(uru)\}, \quad a \in \Sigma \\ R(b) &\stackrel{\text{def}}{=} \{(x, x) \mid x = x\beta \in G(u) - G(uru), \beta \leq b\}, \quad b \in \mathbf{B}. \end{aligned}$$

The interpretations of compound expressions are defined inductively in the standard way for relational models.

We now show that for any  $t \in T_{\Sigma, \mathbf{B}}$ ,

$$R(t) = \{(x, xy) \mid xy \in G(u) - G(uru), y \in G(t)\} \quad (41)$$

by induction on the structure of  $t$ . For primitive programs  $a$  and tests  $b$ ,

$$\begin{aligned} R(a) &= \{(x, xa\beta) \mid xa\beta \in G(u) - G(uru)\} \\ &= \{(x, x\alpha\beta) \mid x\alpha\beta \in G(u) - G(uru)\} \\ &= \{(x, xy) \mid xy \in G(u) - G(uru), y \in G(a)\}, \\ R(b) &= \{(x, x) \mid x = x\beta \in G(u) - G(uru), \beta \in G(b)\} \\ &= \{(x, x\beta) \mid x\beta \in G(u) - G(uru), \beta \in G(b)\} \\ &= \{(x, xy) \mid xy \in G(u) - G(uru), y \in G(b)\}. \end{aligned}$$

For the constants 0 and 1, we have

$$\begin{aligned} R(0) &= \emptyset \\ &= \{(x, xy) \mid xy \in G(u) - G(uru), y \in G(0)\}, \end{aligned}$$

$$\begin{aligned} R(1) &= \{(x, x) \mid x \in G(u) - G(uru)\} \\ &= \{(x, xy) \mid xy \in G(u) - G(uru), y \in G(1)\}. \end{aligned}$$

For compound expressions,

$$\begin{aligned} R(s+t) &= R(s) \cup R(t) \\ &= \{(x, xy) \mid xy \in G(u) - G(uru), y \in G(s)\} \\ &\quad \cup \{(x, xy) \mid xy \in G(u) - G(uru), y \in G(t)\} \\ &= \{(x, xy) \mid xy \in G(u) - G(uru), y \in G(s) \cup G(t)\} \\ &= \{(x, xy) \mid xy \in G(u) - G(uru), y \in G(s+t)\}, \\ R(st) &= R(s) \circ R(t) \\ &= \{(x, xz) \mid xz \in G(u) - G(uru), z \in G(s)\} \\ &\quad \circ \{(y, yw) \mid yw \in G(u) - G(uru), w \in G(t)\} \\ &= \{(x, xzw) \mid xzw \in G(u) - G(uru), z \in G(s), w \in G(t)\} \\ &= \{(x, xy) \mid xy \in G(u) - G(uru), y \in G(st)\}, \\ R(t^*) &= \bigcup_n R(t^n) \\ &= \bigcup_n \{(x, xy) \mid xy \in G(u) - G(uru), y \in G(t^n)\} \\ &= \{(x, xy) \mid xy \in G(u) - G(uru), y \in \bigcup_n G(t^n)\} \\ &= \{(x, xy) \mid xy \in G(u) - G(uru), y \in G(t^*)\}. \end{aligned}$$

We now show (40). Suppose the left-hand side holds. By (41),

$$R(r) \stackrel{\text{def}}{=} \{(x, xy) \mid xy \in G(u) - G(uru), y \in G(r)\} = \emptyset.$$

By the left-hand side of (40),  $R(p) \subseteq R(q)$ . In particular, for any  $x \in G(p) - G(uru)$ ,  $(\epsilon, x) \in R(p)$ , therefore  $(\epsilon, x) \in R(q)$  as well, thus  $x \in G(q) - G(uru)$ . But this says  $G(p) - G(uru) = G(q) - G(uru)$ , thus  $G(p) \subseteq G(q) \cup G(uru) = G(q + uru)$ . It follows from (39) that the right-hand side of (40) holds.  $\square$

**COROLLARY 4.2.** *KAT is deductively complete for formulas of the form (34) over relational models.*

**PROOF.** If the formula (34) is valid over relational models, then by Theorem 4.1, (38) holds. Since KAT is complete for valid equations,

$$\text{KAT} \vdash p + uru = q + uru.$$

But clearly

$$\text{KAT} \vdash p + uru = q + uru \wedge r = 0 \rightarrow p = q,$$

therefore

$$\text{KAT} \vdash r = 0 \rightarrow p = q.$$

$\square$

## 5. COMPLEXITY

As defined in Section 2.1, the decision problem for PHL is to determine whether a given rule of the form (8) is valid over all relational interpretations. Note that *PSPACE*-hardness does not follow immediately from the *PSPACE*-hardness of the equational theory, since the conclusion  $\{b\} p \{c\}$  is of a restricted form  $q = 0$ . Indeed, E. Cohen has shown [Cohen 1999] that the complexity of valid equations of the form  $q = 0$  in KAT is *NP*-complete.

**THEOREM 5.1.** *The decision problem for PHL is PSPACE-complete.*

**PROOF.** The reduction of Sections 3 and 4 transforms the decision problem for PHL to the problem of the universal validity of Horn formulas of the form (34). As shown in Section 4, this can be reduced to testing the validity of a single equation without premises. The equational theory of KAT is decidable in *PSPACE* [Cohen et al. 1996], thus the decision problem for PHL is in *PSPACE*.

We now show that the problem is *PSPACE*-hard. This holds even if the premises  $\{b_i\} p_i \{c_i\}$  are restricted to refer only to atomic programs, and even if they are restricted to refer only to a single atomic program  $p$ . We give a direct encoding of the computation of a polynomial space-bounded one-tape deterministic Turing machine in an instance of the decision problem for PHL. Our approach is similar to [Halpern and Reif 1983], using the premises  $\{b_i\} p_i \{c_i\}$  to circumvent the determinacy assumption. E. Cohen [Cohen 1999] has given an alternative hardness proof using the universality problem for regular expressions.

Consider the computation of a polynomially-space-bounded one-tape deterministic Turing machine  $M$  on some input  $x$  of length  $n$ . Let  $N$  be a polynomial bound on the amount of space used by  $M$  on input  $x$ . Let  $Q$  be the set of states of  $M$ , let  $\Gamma$  be its tape alphabet, let  $s$  be its start state, and let  $t$  be its unique halt state. We use polynomially many atomic propositional symbols with the following intuitive meanings:

- $T_{i,a}$  “the  $i^{\text{th}}$  tape cell currently contains symbol  $a$ ,”  $0 \leq i \leq N$ ,  $a \in \Gamma$ ,
- $H_i$  “the tape head is currently scanning the  $i^{\text{th}}$  tape cell,”  $0 \leq i \leq N$ ,
- $S_q$  “the machine is currently in state  $q$ ,”  $q \in Q$ .

Let  $p$  be an atomic program. Intuitively,  $p$  represents the action of one step of  $M$ . We will devise a set of assumptions  $\phi_1, \dots, \phi_m$  that will say that  $p$  faithfully models the action of  $M$ . The PCA  $\psi$  will say that if started in state  $s$  on input  $x$ , the program

**while** the current state is not  $t$  **do**  $p$

fails. The PCA  $\psi$  will be a logical consequence of  $\phi_1, \dots, \phi_m$  iff  $M$  does not halt on input  $x$ .

The start configuration of  $M$  on  $x$  consists of a left endmarker  $\vdash$  written on tape cell 0, the input  $x = a_1 \cdots a_n$  written on cells 1 through  $n$ , and the remainder of the tape filled with the blank symbol  $\sqcup$  out to the  $N^{\text{th}}$  cell. The machine starts in state  $s$  scanning the left endmarker. This situation is captured by the propositional formula

$$\text{START} \stackrel{\text{def}}{=} T_{0,\vdash} \wedge \bigwedge_{1 \leq i \leq n} T_{i,a_i} \wedge \bigwedge_{n+1 \leq i \leq N} T_{i,\sqcup} \wedge S_s \wedge H_0.$$

We will need a formula to ensure that  $M$  is in at most one state, that it is scanning at most one tape cell, and that there is at most one symbol written on each tape cell:

$$\text{FORMAT} \stackrel{\text{def}}{=} \bigwedge_{0 \leq i \leq N} \bigwedge_{a \neq b} \neg(T_{i,a} \wedge T_{i,b}) \wedge \bigwedge_{p \neq q} \neg(S_p \wedge S_q) \\ \wedge \bigwedge_{0 \leq i < j \leq N} \neg(H_i \wedge H_j).$$

We include the PCA

$$\{\text{FORMAT}\} p \{\text{FORMAT}\}$$

as one of the assumptions  $\phi_i$  to ensure that **FORMAT** is an invariant of  $p$  and therefore preserved throughout the simulation of  $M$ .

Suppose the transition function of  $M$  says that when scanning a cell containing symbol  $a$  in state  $p$ ,  $M$  prints the symbol  $b$  on that cell, moves right, and enters state  $q$ . We capture this constraint by the family of PCAs

$$\{T_{i,a} \wedge H_i \wedge S_p\} p \{T_{i,b} \wedge H_{i+1} \wedge S_q\}, \quad 0 \leq i \leq N-1.$$

All these PCAs are included for each possible transition of the machine; there are only polynomially many in all.

We must also ensure that the symbols on tape cells not currently being scanned do not change; this is accomplished by the family of PCAs

$$\{T_{i,a} \wedge \neg H_i\} p \{T_{i,a}\}, \quad 0 \leq i \leq N, \quad a \in \Gamma.$$

These are the assumptions  $\phi_1, \dots, \phi_m$  in our instance of the decision problem. It is apparent that under any interpretation of  $p$  satisfying these PCAs, successive executions of  $p$  starting from any state satisfying **START**  $\wedge$  **FORMAT** move only to states whose values for the atomic propositions  $S_q$ ,  $T_{i,a}$ , and  $H_i$  model valid configurations of  $M$ , and the values change in such a way as to model the computation of  $M$ . Thus there is a reachable state satisfying  $S_t$  iff  $M$  halts on  $x$ .

We take as our conclusion  $\psi$  the PCA

$$\{\text{START} \wedge \text{FORMAT}\} \text{while } \neg S_t \text{ do } p \{\text{FALSE}\},$$

which says intuitively that when started in the start configuration, repeatedly executing  $p$  will never cause  $M$  to enter state  $t$ . The PCA  $\psi$  is therefore a logical consequence of  $\phi_1, \dots, \phi_m$  iff  $M$  does not halt on  $x$ .  $\square$
