- To recommend a talk, do the same.

Radial Basis Function Interpolation with Bound Constraints

David Bindel

Department of Computer Science
Cornell University

15 September 2014

Background: Surrogate-based global optimization

Goal: Optimize

$$f : \Omega \subset \mathbb{R}^n \rightarrow \mathbb{R}$$

Assume

- Ω compact (usually a rectangular prism)
- f may be “nice”, but is black-box
- Evaluating f is expensive

Idea: Sample, fit a surrogate \hat{f} , repeat.

Motivation: Partial information and gray boxes

$$\frac{\max(1, 1 - 50x^2)}{1 + 25x^2} \leq \frac{\cos(10x)}{1 + 25x^2} \leq \frac{\min(-1, 1 - 50x^2 + 10^4/24x^4)}{1 + 25x^2}$$

Motivation: Partial information and gray boxes

Costly to compute $f(x)$, but may get bounds fast:

- Trivial bounds (e.g. $0 \leq f(x) \leq 1$)
- Nontrivial-but-cheap bounds (e.g. via Taylor expansion)
- Iterates of a solver (e.g. via bisection)
- Partial sum of a separable function, e.g.

$$f(x) = \sum_{j=1}^m \|g(x_j) - g_j\|^2$$

Goal:

- Incorporate bounds into surrogate (today).
- Don't finish unpromising evaluations (another time).

Example: Cubic splines

<http://www.duckworksmagazine.com/03/r/articles/splineducks/splineDucks.htm>

Cubic splines and beam bending

- Bending energy for a beam is:

$$\Psi[u] = \frac{1}{2} \int_{\alpha}^{\beta} (u''(x))^2 dx$$

Natural spline minimizes energy subject to interpolation.

- Equivalently, (natural) spline satisfies the beam equation

$$u'''' = 0$$

between interpolation points, with BCs $u''(\alpha) = u''(\beta) = 0$.

- Solution is twice differentiable and piecewise cubic.

A particular parameterization

For $f : [\alpha, \beta] \rightarrow \mathbb{R}$ and $\alpha = x_1 < x_2 < \dots < x_N = \beta$

$$s(x) = a_0 + a_1x + \sum_{j=1}^N c_j |x - x_j|^3$$

This is a C^2 piecewise cubic. How to make a natural spline?

- Set coefficients to satisfy $s(x_j) = f(x_j)$.
- Set $s'' = \pm 6 \sum_{j=1}^n c_j (x - x_j) = 0$ at $x \in \{\alpha, \beta\}$.
- Equivalently, add “discrete orthogonality” constraints

$$\sum_{j=1}^N c_j = 0$$

$$\sum_{j=1}^N c_j x_j = 0.$$

A particular parameterization

Actually have

$$\Psi[s] = \frac{1}{6} \sum_{j,k} c_j c_k |x_j - x_k|^3 = \frac{1}{6} c^T \Phi c$$

for any natural spline, where $\Phi_{ij} = |x_i - x_j|^3$.

Minimize Ψ subject to $\Pi^T c = 0$, where

$$\Pi^T = \begin{bmatrix} 1 & 1 & \dots & 1 \\ x_1 & x_2 & \dots & x_N \end{bmatrix}$$

KKT conditions are

$$\begin{bmatrix} \Phi & \Pi \\ \Pi^T & 0 \end{bmatrix} \begin{bmatrix} c \\ a \end{bmatrix} = \begin{bmatrix} f_X \\ 0 \end{bmatrix}$$

Beyond cubic splines

<http://step.polytml.ca/~rv101/thinplates/>

$$\Psi[u] = \frac{1}{2} \int_{\Omega} (\nabla^2 u)^2 d\Omega$$

Radial basis function (RBF) approximation

Functional form of interpolant:

$$s(x) = \sum_{j=1}^N c_j \phi(\|x - x_j\|) + p(x)$$

- $X = \{x_i\}_{i=1}^N$ is the set of *centers*
- $\phi : \mathbb{R} \rightarrow \mathbb{R}$ is a *radial basis function*
- $p \in \mathcal{P}_{d-1}$ is a *polynomial tail*

RBF interpolation

Functional form:

$$s(x) = \sum_{j=1}^N c_j \phi(\|x - x_j\|) + p(x)$$

Interpolation constraints:

$$s(x_i) = f(x_i), \quad i = 1, \dots, N$$

Discrete orthogonality:

$$\sum_{j=1}^N c_j q(x_j) = 0, \quad \forall q \in \mathcal{P}_{d-1}$$

RBF interpolation

Given basis $\{p_j(x)\}$ for \mathcal{P}_{d-1} , interpolation system is

$$\begin{bmatrix} \Phi & \Pi \\ \Pi^T & 0 \end{bmatrix} \begin{bmatrix} c \\ a \end{bmatrix} = \begin{bmatrix} f_X \\ 0 \end{bmatrix}$$

where

- $c = [c_1 \ \dots \ c_N]^T$ is the coefficient vector
- $p(x) = \sum_j a_j p_j(x)$ is the polynomial tail
- $\Pi_{ij} = p_j(x_i)$
- $\Phi_{ij} = \phi(\|x_i - x_j\|)$

When is this well posed? When is there an “energy”?

Conditional positive definite RBFs

[Micchelli, 1986]: ϕ is *conditionally positive definite of order d* if for all $X = \{x_1, \dots, x_N\}$ distinct and $c \neq 0$ s.t.

$$\sum_{j=1}^N c_j q(x_j) = 0, \quad \forall q \in \mathcal{P}_{d-1},$$

we have that

$$\sum_{i,j} c_i c_j \phi(\|x_i - x_j\|) > 0$$

Conditional positive definite RBFs

		$\phi(r)$	Order
Cubic	Schoenberg, 1946	r^3	2
Thin-plate	Duchon, 1976	$r^2 \log r$	2
Multiquadric	Hardy, 1968	$-\sqrt{\gamma^2 + r^2}$	1
Inverse multiquadric		$(\gamma^2 + r^2)^{-1/2}$	0
Gaussian		$\exp(-r^2/\gamma^2)$	0

Conditional positive definite RBFs

For an appropriate degree tail, the interpolation system

$$\begin{bmatrix} \Phi & \Pi \\ \Pi^T & 0 \end{bmatrix} \begin{bmatrix} c \\ a \end{bmatrix} = \begin{bmatrix} f_X \\ 0 \end{bmatrix}$$

is the KKT system for

$$\min \frac{1}{2} c^T \Phi c - c^T f_X \quad \text{s.t.} \quad \Pi^T c = 0.$$

Optimization well-posed if Π is full rank

$\equiv q \in \mathcal{P}_{d-1}$ uniquely identified by values on X .

Physically: Problem is statically determinate (no rigid-body modes).

Energy interpretation

Two splines with form

$$s(x) = \sum_{j=1}^N c_j \phi(\|x - x_j\|) + p(x)$$

Define a semi-definite form (“energy semi-inner product”)

$$(s, \tilde{s}) = \sum_{j,k} c_j \tilde{c}_k \phi(\|x_j - x_k\|)$$

Corresponding semi-norm is $|s| = (s, s)^{1/2}$.

Native space \equiv closure of set of splines under semi-norm.

Interpolating spline minimizes $|s|$ under interpolation constraints.

Dual variables

Semi-definite form is also

$$\begin{aligned}(s, \tilde{s}) &= \sum_{j,k} c_j \tilde{c}_k \phi(\|x_j - x_k\|) \\ &= \sum_j c_j \left(\sum_k \tilde{c}_k \phi(\|x_j - x_k\|) \right) \\ &= \sum_j c_j (\tilde{s}(x_j) - \tilde{p}(x_j)) \\ &= \sum_j c_j \tilde{s}(x_j)\end{aligned}$$

Think of $\tilde{s}(x_j)$ as displacement, c_j as force.

Incorporating bounds

Set $X = E \cup B$ where

$$E = \{x_j\}_{j=1}^{|E|},$$

$$s(x_i) = f(x_i)$$

$$B = \{x'_j\}_{j=1}^{|B|},$$

$$-\infty \leq \ell_i \leq s(x_i) \leq u_i \leq \infty.$$

and minimize $|s|$ subject to these constraints. KKT conditions:

$$s(x_i) = f(x_i)$$

$$s(x'_i) = \ell_i \implies c'_i \geq 0$$

$$s(x'_i) = u_i \implies c'_i \leq 0$$

$$\ell_i \leq s(x'_i) \leq u_i \implies c'_i = 0.$$

Include “forces” (nonzero coeffs) to push surface within bounds.

Incorporating bounds

Correction formulation

Suppose

$s_0(x)$ = spline with only interpolation

$s(x)$ = spline with interpolation + bounds

$$= s_0(x) + G(x)$$

Note that

$$|s|^2 = |s_0|^2 + 2(s_0, G) + |G|^2 = |s_0|^2 + |G|^2.$$

Minimizing $|G|$ means minimizing $|s_0|$

Error analysis

Set

$f \in$ native space for ϕ

$s(x) =$ spline with only interpolation

$\tilde{s}(x) =$ spline with interpolation + bounds

Standard analysis: bound error semi-norm $|f - s|$ and apply

$$|f(x) - s(x)| \leq P(x)|f - s| \quad |f(x) - \tilde{s}(x)| \leq P(x)|f - \tilde{s}|$$

Error:

$$\begin{aligned} |f - s|^2 &= |(f - \tilde{s}) + (\tilde{s} - s)|^2 = |f - \tilde{s} + G|^2 \\ &= |f - \tilde{s}|^2 + 2(f - \tilde{s}, G) + |G|^2. \end{aligned}$$

Error analysis

Write inner product term as

$$(f - \tilde{s}, G) = \sum_{j=1}^{|B|} (f(x_j) - \tilde{s}(x_j)) c'_j$$

and complementarity yields

$$c'_i > 0 \implies \tilde{s}(x_i) = \ell_i \leq f(x_i)$$

$$c'_i < 0 \implies \tilde{s}(x_i) = u_i \geq f(x_i)$$

Either way,

$$(f(x_i) - \tilde{s}(x_i)) c'_i \geq 0.$$

Therefore $(f - \tilde{s}, G) \geq 0$, and so

$$\begin{aligned} |f - \tilde{s}|^2 &= |f - s|^2 - 2(f - \tilde{s}, G) - |G|^2 \\ &\leq |f - s|^2 - |G|^2 \end{aligned}$$

Error example

Correction formulation, concretely

Coefficients for G satisfy

$$\begin{bmatrix} \Phi_{BB} & \Phi_{BE} & \Pi_B \\ \Phi_{EB} & \Phi_{EE} & \Pi_E \\ \Pi_B^T & \Pi_E^T & 0 \end{bmatrix} \begin{bmatrix} c' \\ \Delta c \\ \Delta a \end{bmatrix} = \begin{bmatrix} g \\ 0 \\ 0 \end{bmatrix}$$

where $g = G_B$ satisfies $\hat{\ell} \leq g \leq \hat{u}$ for $\hat{\ell} = \ell - s_X$ and $\hat{u} = u - s_X$.

Eliminate Δc and Δa to get Schur complement

$$S = \Phi_{BB} - [\Phi_{BE} \quad \Pi_B] \begin{bmatrix} \Phi_{EE} & \Pi_E \\ \Pi_E^T & 0 \end{bmatrix}^{-1} \begin{bmatrix} \Phi_{EB} \\ \Pi_B^T \end{bmatrix}$$

Now c' minimizes $(c')^T S c'$ subject to $\hat{\ell} \leq g \leq \hat{u}$.

Mixed Gaussian elimination

Rewrite correction system matrix as

$$\begin{bmatrix} 0 & \Pi_E^T & \Pi_B^T \\ \Pi_E & \Phi_{EE} & \Phi_{EB} \\ \Pi_B & \Phi_{BE} & \Phi_{BB} \end{bmatrix} = \begin{bmatrix} A & B \\ B & \Phi_{BB} \end{bmatrix} = \begin{bmatrix} P & 0 \\ 0 & I \end{bmatrix}^T \begin{bmatrix} L_{11} & 0 \\ L_{21} & I \end{bmatrix} \begin{bmatrix} U_{11} & U_{12} \\ 0 & S \end{bmatrix}$$

Now run usual forward/backward substitution:

$$y := L_{11}^{-1} P_{11} f_E$$

$$f_B^0 := L_{21} y$$

$$\hat{\ell} := \ell - f_B^0$$

$$\hat{u} := u - f_B^0$$

$$c' := \operatorname{argmin}_d \{d^T S d : \hat{\ell} \leq S d \leq \hat{u}\}$$

$$\bar{c} := U_{11}^{-1} (y - U_{12} c_B)$$

Mixed Gaussian elimination

Use active set method to solve

$$c' = \operatorname{argmin}_d \{d^T S d : \hat{\ell} \leq S d \leq \hat{u}\}$$

- Allows warm-start in context of global optimization.
- Maintain $QSQ^T = R^T R$.
- Permutation Q moves free variables toward front.
- Update Q and R in $O(N^2)$ time per iteration.
(Actually $O(Nm)$ where m is distance variable moves.)

Adding points or updating bounds tends to be cheap.

Example: Capped surfaces

Consider

$$f(x, y) = \sum_{j=1}^{10} [2 + 2j - \exp(jx) - \exp(jy)]^2$$

- Large function values can cause interpolant to oscillate
- Idea: replace large function values with a “cap”
- Hard cap: interpolate $\min(f(x, y), M)$
- Soft cap: replace large $f(x_i, y_i)$ with $f(x_i, y_i) \geq M$

Cubic

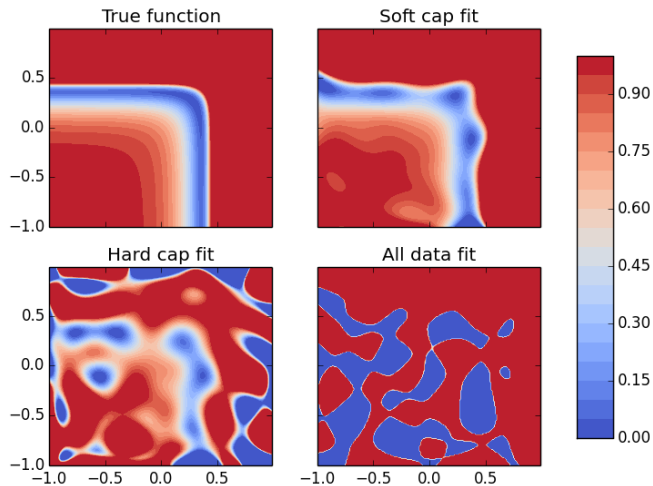

Thin-plate

Multiquadric

Gaussian

Conclusions

- Energy interpretation of RBF interpolant
⇒ Easy to add upper/lower bounds at points
- Python+C code (PyRBFbound) is now public on BitBucket:

`https://bitbucket.org/dbindel/pyrbfbound/`

- ArXiv preprint on the method should be linked soon
- Lots of possible extensions
 - Point bounds + RBF-QR and contour-Padé interpolation
 - Incorporation with scalable solvers (e.g. FMM) for 2D/3D
 - Enforcing continuous lower/upper bounds, integral bounds
