Supplementary Material for: "Discovering Underground Maps from Fashion"

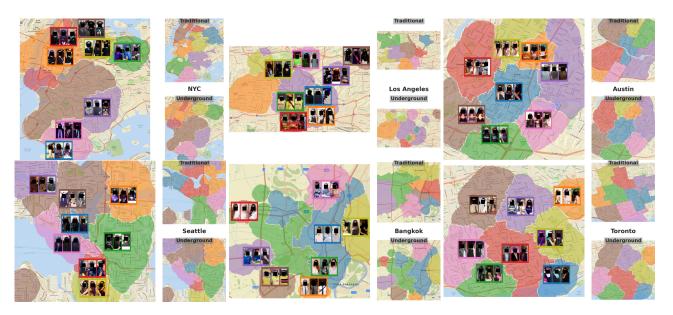

Figure 1: Underground maps in contrast with the traditional maps for 6 cities. Our method can discover neighborhoods based on activities like student neighborhoods in Los Angeles (red), Austin (orange) and Seattle (orange) by looking at the fashion sense. It also discovers tourist neighborhoods of NYC (red), Seattle (Pink).

In this supplementary document we present some of the results that we could not present in the main paper. Please also refer to the **video** along with this supplementary to explore a wide range of results. The video can be found at http://www.cs.cornell.edu/~utkarshm/underground_maps/supplementary_video.mp4

Sec. 1 shows underground maps for many cities discovered by our method. In Sec. 2, we present additional implementation details about the benchmark creation and getting unbiased locations. Sec. 3 refers to the list of cities used for different types of analysis in our results. In Sec. 4 we break down the performance of our method further for each city and for each class of HM benchmark. In Sec 5 we conduct various ablation studies by measuring the effect of different hyperparameters on our method. Sec. 6 shows how we collected data for experiments with local human judges. Finally, in Sec. 7 we present additional qualitative results of unique, similar, and analogical neighborhoods found by our method.

1. Underground Maps

Figure 1 shows the underground maps for 6 cities and contrasts them with their traditional maps. Our method discovers similarity across regions that are geographically far apart. For example, for Bangkok it finds 2 regions (colored blue) that are geographically far away, but people wear similar clothing. Also these maps have very different boundaries than a traditional map.

Figures 6 and 7 show the underground maps for 32 cities excluding the cities where traditional maps were available. Again, our method discovers similarity across regions that are geographically far apart, and can find some very specific neighborhoods. In Madrid, we discover 2 neighborhoods with stadiums and fans of two different football clubs Real Madrid (green) and Athletico Madrid (pink). These neighborhoods are different from other neighborhoods in the city, like the neighborhood with many nightclubs and pubs (red).

2. Additional Implementation Details

2.1. Creation of BD Benchmark

In this section we present more information on how the BD Benchmark is created.

To create regions over maps using business density, we follow our method from Sec. 3 (main paper), with a few differences. First, since we need to segment on the basis of business density, the featurization of a region on the map is the normalized histogram of different businesses. Second, to keep the similarity of the two benchmarks, rather than sampling a circular radius around a point, we sample a square region of length and width 0.01° . Finally, we do not know the number of neighborhoods (unlike the HoodMaps Benchmark, where the number of labels is given). So we use affinity propagation for clustering instead of K-means to find the ideal number of neighborhoods per city. Affinity propagation produces a min/max/median of 3/6/6 types of regions per city.

2.2. Getting Unbiased Locations

The samples within the radius r are not going to be distributed uniformly around x. These samples will be biased towards certain directions on the map. For example, if we sample for a location at the junction of land and sea, almost no images will be sampled from sea, hence, the location of the image samples would be biased towards land. The mean of the sampled image location would be the coordinate for which these samples are unbiased. Therefore, we use the new unbiased location in the pipeline instead of the sampling location, and we use h_x as the histogram description for this unbiased location. T(x) are the set of images that describes the sampled location x:

$$T(x) = \{I_i : ||l_i - x||_2 < r\}$$
(1)

The unbiased location is:

$$x' = \sum_{I_i \in T(x)} l_i \tag{2}$$

3. List of Cities

Austin	Bangkok	Beijing	Berlin	Bogotà	Budapest	Buenos Aires	Cairo
Chicago	Delhi	Dhaka	Guangzhou	Istanbul	Jakarta	Johannesburg	Karachi
Kyiv	Kolkata	Lagos	London	Los Angeles	Madrid	Manila	Mexico City
Milan	Moscow	Mumbai	Nairobi	NYC	Osaka	Paris	Rio
Rome	São Paulo	Seattle	Seoul	Shanghai	Singapore	Sofia	Sydney
Tianjin	Tokyo	Toronto	Vancouver				

Table 1: Cities in our analysis. Cities colored blue and red are evaluated quantitatively using both the HM and BD benchmarks. Cities colored red have administrative boundary data available and so are evaluated for the right hand side of Table 1 in the main paper.

Table 1 presents the list of 44 cities from GeoStyle. 37 of these 44 cities have enough data available on HoodMaps for us to use. We do the quantitative analysis on all 37 of these cities using HM and BD benchmarks. The 8 cities marked red are where we can get publicly available administrative boundary information.

4. Quantitative Performance Breakdown

4.1. Per-Class Performance for HM Benchmark

We also compare Per-Class performance against the Admin baseline for the 8 cities. Table 2 compares MMIoU for these cities. Our method finds it difficult to discover corporate neighborhoods, while it is better at understanding hipster neighborhoods for these cities. We believe this is because fewer people are posting images of themselves from a corporate environment.

4.2. Per-city Performance

Figure 2 shows the per-city purity measure comparing our method against the best-performing baseline (PID) for the HM benchmark. PID performs better than our method for the cities to the left and our method outperforms PID for the cities to the

	Wea.	Hip.	Tou.	Stu.	Nor.	Cor.
Admin Ours	0.315 0.306		0.269 0.294			

Table 2: Per class accuracy on HoodMaps (MMIoU) for 8 cities where Admin data is available. On average our method performs better than admin baseline, But our method finds it difficult to find corporate neighborhoods as fewer people post pictures of themselves from a corporate environment.

right. Figure 3 similarly compares our method against admin baseline (PID) for the 8 cities over the HM benchmark. Our method performs better than admin for all the cities.

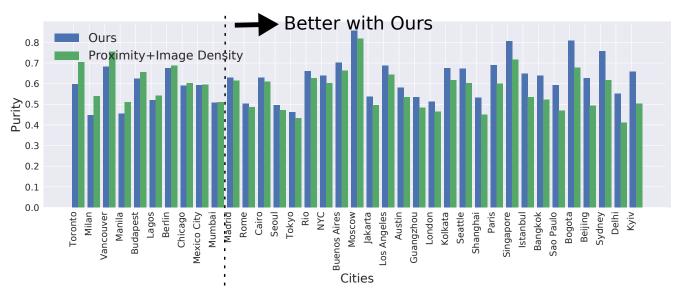

Figure 2: Performance (purity over HM benchmark) of our method against the PID baseline for individual cities. The cities are sorted from left to right by the cities where PID performs best to the cities where our method performs the best. For 27 out of 37 cities, we perform better than the PID baseline.

Figure 3: Performance (purity over HM benchmark) of our method against the Admin baseline for all 8 cities where Admin is available. The cities are sorted from left to right by the increasing gain of our method. Our method performs better than Admin for all the cities.

5. Ablation Studies

5.1. Effect of Radius r

We look at how changing the sampling radius affects the performance of our method on the two benchmarks. We increase and decrease the radius by a factor of $\sqrt{2}$. Table 3 shows the performance of our method with changing radius r. The best performance is at r=0.020. However, as can be seen by the performance on BD benchmark, changing the radius does not have a huge impact on the performance.

	Н	M Bench	mark	В	D Benchi	nark
r	NMI	Purity	MMIoU	NMI	Purity	MMIoU
0.010	0.185	0.607	0.212	0.293	0.580	0.306
0.014	0.216	0.599	0.238	0.347	0.599	0.336
0.020	0.260	0.635	0.272	0.369	0.597	0.339
0.028	0.246	0.573	0.257	0.369	0.598	0.332
0.04	0.240	0.584	0.254	0.350	0.576	0.325

Table 3: Effect of changing sampling radius r on the performance of neighborhood discovery.

5.2. Number of Discovered Clusters

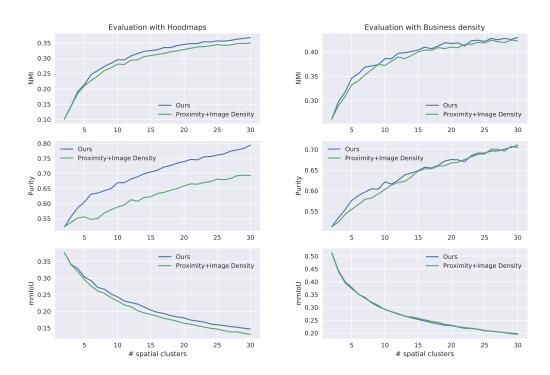

Figure 4: Performance (NMI, Purity and MMIoI) of our method against the PID baseline when varying the number of discovered clusters for HM (left) and BD (right). Our method outperforms the best baseline on all metrics and can be used to discover any number of neighborhoods in a city.

In this section we see how changing the number of spatial clusters affects performance on the evaluation metric. Figure 4 shows the performance when sweeping over the number of spatial clusters for all three unsupervised evaluation metrics over

the two benchmarks. Our method consistently outperforms the baseline method for all metrics (performs on par for MMIoU for the BD benchmark). Hence our conclusions are stable with respect to this parameter setting.

6. Experiments with Humans Judges

We restrict the Amazon Mechanical Turk workers to perform tasks for cities of their country (approximate way of enforcing a "local" person). Additionally, we add sentinels in our tasks, by duplicating 4 questions out of 20. If the 2 clicked points for the same question are far apart from each other, we do not consider the answers of that worker.

Figure 5 shows the interface as seen by the Mechanical Turk workers. Workers are supposed to look at the set of images as shown on the right and click on the point where they think the images come from (red marker on map). Workers are allowed to zoom in/out on the map, and redo a previously selected image. We additionally also ask for a confidence rating for a click. Note that it is not visible to the workers which method (ours or the baseline) has produced the images. They are simply asked to localize the styles they see.

Figure 5: Interface seen by the Amazon Mechanical Turk workers. The instructions can be seen on the top.

7. More Qualitative Results

7.1. Examples of Unique Neighborhoods

Table 4 shows the list of the top 40 most unique neighborhoods found by our methods. It shows unique regions such as neighborhoods with sports stadiums (Los Angeles, Milan, Chicago, Seattle), tourist areas (Bogota, Beijing (second neighborhood)), beaches (NYC, Sydney (fourth neighborhood)) etc.

7.2. Examples of Similar Neighborhoods

Table 5 shows the list of the top 20 most similar neighborhoods found by our methods. It shows similar neighborhoods with tourists (Kyiv-Moscow, Chicago-NYC (first pair)), nightlife (Chicago-NYC (second pair), NYC-Toronto). Note that this measure of similarity only find pairs that are geographically close (due to similar weather and culture).

7.3. Examples of Analogical Neighborhoods

Table 6 shows the list of the top 20 tuples of contextually similar neighborhoods, where non-contextual similarity fails to give good similar neighborhoods. The first and second column are our contextually similar neighborhoods. The third column shows the neighborhood produced by simpler similarity search. Note that most of the pairs are from cities that are geographically far (where non-contextual similarity faces more challenges). The first example finds similar tourist regions in culturally different cities Istanbul (neighborhood around Hagia Sophia) and Rome (neighborhoods around Colosseum and Vatican City).

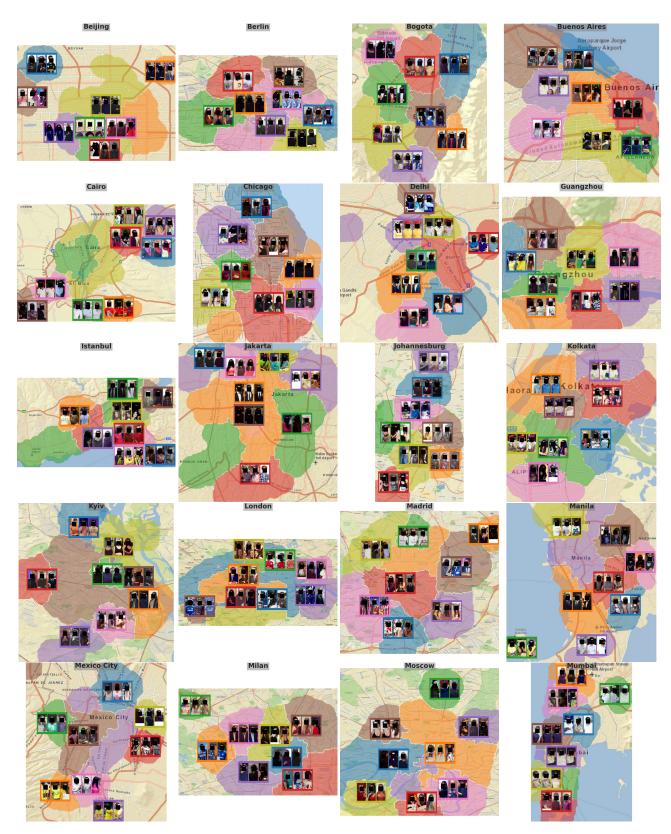

Figure 6: Underground maps for 20 the cities. Our model uses fashion to discover neighborhoods of cities. For example, in Madrid (green and pink) and London (brown and green) we discover neighborhoods with sports arenas. We also discover tourists areas in cities such as Beijing (red) and Istanbul (purple).

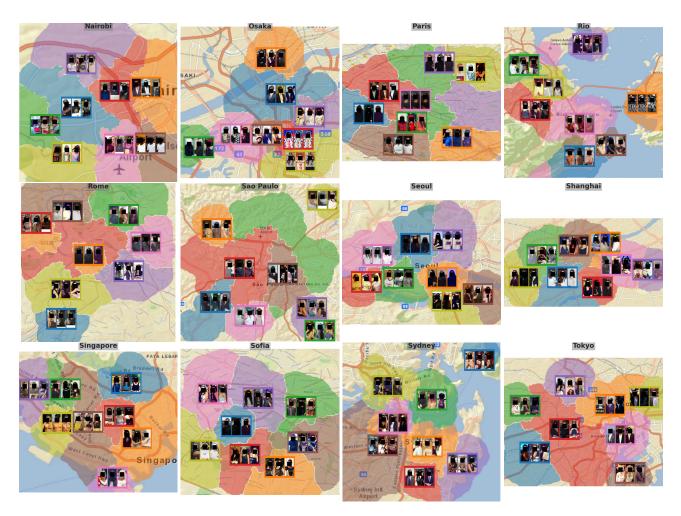

Figure 7: Underground maps for 12 more cities. We discover popular beaches in Rio (blue) and Sydney (purple). We also discover two geopgraphically apart tourist regions in Rome (orange).

Table 6: Top 20 most contextually similar neighborhoods (left pairs), where simpler similarity results in a different neighborhood (right). As can be seen from the examples, this is typically the case when 2 cities are geographically and culturally far apart. For instance, in the first example two tourist neighborhoods of Istanbul and Rome are correctly identified as similar, but they are not found without contextual encoding. Top attributes are the relatively most frequent attributes common in the two neighborhoods.
